A Follow-up of Children Discharged from a Psychiatric Ward

W. D. WOLKING, M.A., W. QUAST, B.S.,
GLORIA BURIAN, B.A., R. A. JENSEN, M.D.
Minneapolis, Minnesota

RESEARCH on the effects and outcome of psychiatric treatment* has been limited, and much of what has been done lacks scope, clarity, and quality. Miles et al.¹ reported a critical review of thirty-five studies dealing with the outcome of psychiatric treatments in 1950. They noted that these studies did not state their criteria for judging improvement clearly, if at all; they were generally not comparable; and their mean results tended to approximate the spontaneous recovery rate of neurotic patients from mental hospitals.

When the area of concern is narrowed to the outcome of psychiatric treatment of child patients, the literature is even more meager. Witmer² in an early study concluded that the parents' emotional adjustment is the most important variable for recovery. Her paper is important in that she tried to establish explicit criteria for basing judgments of improvement. Hardcastle³ reported a follow-up study in which 64 per cent of the children were improved. Benjamin and Weatherly⁴ reported on follow-up studies done by Camper⁵ and Gordon⁶ on the first forty-eight patients discharged from the Children's Ward of the Illinois Neuropsychiatric Institute. Using a relative criteria of change, they found one-fourth greatly improved after a period of from two to five years after discharge. One-fifth showed no improvement, while 46 per cent showed either slight or moderate improvement. This was after an average stay of 9.3 months in hospital. Gordon found no relationship between categories of background and pre-ward environment and the current adjustment of the children. Thus, major emphasis was placed on the treatment as the main

determiner of outcome. Camper found an optimum stay of seven to nine months on the ward; a maximum number of individual treatment hours with both child and his parents; and the degree of change of the parents' attitudes to be correlated positively with the children's adjustment.

Cohen and Carper⁷ conducted a survey of 2,419 cases seen by the traveling clinics of the New York State Department of Mental Hygiene Child Guidance Clinics during 1938 and 1939. Although these were outpatients, as contrasted to inpatients in the present study, this work is of special interest because these clinics were largely limited to diagnosis and disposition at that time, thus functioning much like our inpatient service at Minnesota. Of the 1,859 cases successfully followed, 44.3 per cent were considered adjusted, 8 per cent much improved, 27.3 per cent improved, and 20.4 per cent unimproved. They found favorable prognoses tended to be associated with diagnosis of speech, social, primary behavior, and educational problems. Poor prognoses tended to be the rule for psychopathic personalities and mental defectives.

The present investigation was undertaken primarily to provide information which our staff could use in evaluating our first years of operation as an inpatient service. We hoped to get rough estimates of the changes which had taken place in the children studied and planned for on the Child Psychiatry Station at the University of Minnesota Hospitals. A basic interest was to provide the parents of our patients an opportunity to criticize the procedures of the services and to offer suggestions for improvements. Only minor attention was accorded the problem of which factors were responsible for the changes in the children in this preliminary and unbudgeted study.

As was true of the studies reviewed, no attempt was made to provide for a control group. A controlled design would give information on the

From the University of Minnesota Medical School, Division of Child Psychiatry, Minneapolis, Minnesota.

*Treatment is used here in a broad sense to include those psychiatric services which function mainly to diagnose and formulate treatment plans which are largely carried out by other physicians, agencies, or persons as well as those offering a more direct therapy.

spontaneous recovery rate and the efficacy of our psychiatric procedures above and beyond the natural curative powers inherent in developing children and their environs.**

Description of the Child Psychiatry Ward and its Operation

The Child Psychiatry Station, opened in October, 1952, occupies one wing of the sixth floor of the University of Minnesota Hospitals. It is a closed ward with single and double rooms to accommodate a total of fourteen boys and girls under the age of sixteen. The station also includes two recreational rooms and lounges, an arts and crafts workshop, a small kitchen, a nurses' station, and the associated service rooms.† The permanent staff includes three physicians, two psychologists, one psychiatric social worker, a public school teacher, an occupational therapist, a teaching assistant, nurses, aides, and orderlies. There are usually two resident physicians on the service (one from pediatrics and one from psychiatry).

Administratively Child Psychiatry is a division of the Department of Pediatrics, but works closely with the Department of Psychiatry with the senior staff holding joint appointments to both departments. The station and its operation is an integral part of the medical school program and student physicians, as well as resident physicians, are assigned to all patients.

Up to this time the service has functioned mainly as a diagnostic study center for the state of Minnesota. As a rule, children are admitted for approximately one month, during which time a thorough study is done following which a treatment plan is formulated and implemented. Many of the patients are followed on an outpatient basis subsequent to their discharge from the hospital; however, many are referred to other clinics or agencies or to their local physician for continued treatment. A few selected children have been maintained on the station for three to six months of inpatient treatment.

**See: Rosenthal, D. and Frank, J. D.: Psychotherapy and the placebo effect. *Psych. Bull.*, 294-302, 1956, for references on experimental designs in evaluating psychotherapy.

†Starting in August, 1956, the Child Psychiatry Station will be remodeled and expanded to provide for a total capacity of twenty-two patients. It will include a new nurses' station with visual control through safety glass enclosures, a new dining room and quiet lounge, a new school room, a greatly expanded and well equipped arts and crafts workshop, an outdoor play area, and new offices, laundry and kitchen facilities.

Total		126	71	197	

The psychiatric unit tends to serve as a last resort for the problem children of the state, with many referrals coming from physicians or clinics that regard inpatient psychiatric study and the consulting services essential to handle particular problem children. For this reason our population may differ from the community child guidance clinic in that more children with serious mental and emotional disturbances and organic diseases of the central nervous system are studied.

The Follow-Up Study

Arbitrarily, it was decided to obtain information pertaining to present adjustment on the first two hundred children studied and discharged from the service. The post-discharge period ranged from six to twenty-seven months with a mean of approximately seventeen months. Of the two hundred patients one was deceased and the whereabouts of two was unknown, so that the working sample was 197 children. Table I gives the grouped data on sex, age and intelligence. As noted in the table, the sample was broken into two groups: (1) the major group of behavioral problems, and (2) the severe mental defectives.

Although not typical of studies reviewed, this dichotomy was made in recognition of our sizable group of mental defectives and the relative unmodifiability of their basic problem—low intelligence. As noted below, 5.6 per cent of the major group received formal diagnoses of mental deficiency. These were cases of mild retardation with behavior problems prominent in their presenting complaints, as compared to complaints of inability to learn or school failure for those cases included in the defective group.

The diagnoses of the major group included: organic brain damage (12.4 per cent), psychosis (5.0 per cent), psychoneurosis (9.3 per cent), psychophysiologic reaction (3.7 per cent), personality disorder (21.1 per cent), speech disorder (0.6 per cent), mental deficiency, mild (5.6 per cent), transient situational personality disorder

(39.8 per cent), and no disease or diagnosis deferred (2.5 per cent). Presenting complaints ran the gamut of usual complaints and "admission tickets." All socio-economic classes were represented, but there was an overweighting of lower middle class and lower class families in this group. Sixty-five children came from broken homes; ninety-six came from more or less normal and intact homes. These patients had 2.8 siblings on the average. Of this group, 115, or 71.4 per cent, had negative physical examinations, twenty-six, or 16.1 per cent, had positive neurologic findings. The remainder had a variety of physical or sensory defects. Electroencephalograms were normal or near normal for ninety-nine, or 70.3 per cent, abnormal for forty-two, or 29.7 per cent. Twenty children did not have EEG's reported. The mean length of hospitalization for the group was 27.3 days.

The presenting complaints of the mental defective group ranged from "slow to learn" through "speech difficulty" to "behavior problem," and included a few with physical complaints. All socio-economic classes were represented with a slight overweighting of the upper middle class families. Five of these children came from broken homes, while the rest came from more or less normal homes. There was a mean of 2.7 siblings per patient, and their mean length of hospitalization was 13.8 days.

All of the information gathered on the follow-up was obtained by questionnaire. The questionnaire for the major group asked for the child's present living status; at home, boarding school, foster home, state institution, et cetera. If the child was not living at home, a new questionnaire was mailed to the responsible adult. The first section of this questionnaire asked the parent or surrogate to rate the child on six, five-point rating scales. The scales were: (a) How has he changed since he left the hospital?, (b) How does he get along with the family?, (c) How does he do in his studies at school?, (d) How is his behavior in school?, (e) How does he get along with other children?, and (f) How does he feel about himself? All rating scales allowed one position for worse, one for the same, and three for various degrees of improvement. The raters were asked to base their ratings on the child's behavior for the past two months as compared with when they brought him to the hospital. The second section of this instrument asked: (a) What do you think caused any changes for the better, if present?, (b) Have you consulted any

other physicians or agencies about the same problem since the hospitalization?, and (c) What improvements can we make to render maximum service to the children and their families? The last was composed of a check list and space for suggestions.

A shorter form of the questionnaire, which omitted the ratings of present adjustment, was mailed to the parents of the thirty-six children diagnosed seriously mentally defective. This form included a question about the child's school attendance and one designed to elicit information about what action the parents had taken in their retarded child's behalf.

The questionnaires were mailed out to the patients' parents or parent surrogate with a covering letter which was personalized to include the child's first name and the dates he was hospitalized. This letter was designed to indicate interest in the long range adjustment of the children brought to the hospital and in improving the services to parents of children with similar problems. Each individually typed letter was signed by the chief psychiatrist and the senior psychologist. A special form of the cover letter was drawn up and sent to agencies furnishing the ratings in place of parents. We found Nixon's article⁸ helpful in designing the questionnaire and the cover letter.

For those who did not respond to the first letter, a second and eventually a third form of the cover letter was sent with additional copies of the questionnaire.

Results

One hundred seventy-seven of the 197 questionnaires mailed were returned—an 89.9 per cent rate of return. Four of these were not usable, so the total per cent of usable returns was 87.6 per cent. The first mailing brought approximately 50 per cent returns, the second mailing about 30 per cent, with another 10 per cent following the third request.

Questionnaires for Major Group.—Two distributions of ratings of present adjustment were made. The first was based on ratings on the single item: How has he changed since he was seen at the hospital? The second distribution of adjustment ratings was based on a score derived by summing the weighted ratings for all six adjustment scales. The arbitrary weights assigned were: —1 for worse, 0 for the same, 1 for slight improvement, 2 for marked improvement, and 3 for

TABLE II.

Weighted Adjustment Rating	Male	Female	Total	Per Cent of Total*	
No return or rating not made	18	7	25	15.5	15.5 unknown
-1	4	1	5	3.1	13.7 same or worse
0	14	3	17	10.6	
1	26	16	42	26.1	26.1 slight improvement
2	34	16	50	31.1	44.7 marked improvement
3	12	10	22	13.6	
	108	53	161	100.0	

*These percentages are based on the total sample.

completely over his problem in the area being rated. See Tables II and III for these distributions.

Based on Table II, we find 13.7 per cent of the cases are the same or worse, 26.1 per cent show slight improvement, 44.7 per cent are markedly improved or completely over their problems, and 15.5 per cent are unknown. If the percentages are based on the summated adjustment index, one finds 19.9 per cent the same or worse, 31.1 per cent with slight improvement, and 36.6 per cent markedly improved or having no problems, and 12.4 per cent unknown. It would have been most desirable and interesting to have a matched control group of undiagnosed and untreated problem children against which to compare these percentages of improvement.

An attempt was made to develop a simple prognostic index[‡] based on ratings of the child's symptoms and behavior while in the hospital, as these ratings could be made from material recorded in the regular hospital and psychiatric charts.* The index consisted of five, three-point rating scales covering: (1) malignancy of symptoms, (2) trend of disorder while in the hospital, (3) duration of symptoms, (4) interpersonal relationship with physician, and (5) adjustment to the ward. The positions of the rating scales were arbitrarily weighted equally and added to give a single index. Ratings were made for the entire group of 161 psychiatric cases by one of us. A random sample of twenty-eight cases was rated independently by two of the other authors and reli-

[‡]This index was an adaptation of one worked out by F. D. Thorne: *Principles of Psychological Examining*. J. Clin. Psychol., Brandon, Vermont, 1955, pp. 106-109.

*A tangential concern in this study was to evaluate the potential of the hospital and child psychiatry charts for research purposes. This study clearly indicates the need for modifications to enhance such an objective.

TABLE III.

Weighted Adjustment Indices	Frequency	Per Cent*	
No return or ratings not made	20	12.4	12.4 unknown
-6 thru -1	5	3.1	19.9 same or worse
0 thru 5	27	16.8	
6 thru 11	50	31.1	31.1 slight improvement
12 thru 17	52	32.3	36.6 marked improvement or well
18	7	4.3	
	161	100.0	

*Percentages are based on total sample.

**In a small number of cases, the parent or surrogate had not rated every scale. If at least four of the six scales were rated, the others were prorated in the usual way, with the realization that this may have resulted in an overestimate of adjustment in these cases.

bility coefficients were computed. The corrected Pearson coefficients were .66, .58, and .58, indicating that the inter-rater reliability was not satisfactory. However, the correlations with the adjustment ratings were computed. The Pearson coefficient between the prognostic index and the single rating of adjustment was not significantly different from zero, while the coefficient between the prognostic index and the summated adjustment index was $.30 \pm .08$. Although a low positive relationship exists, it appears that the present prognostic index would not be economical in predicting the later adjustment of our cases.

In a further attempt to locate those variables which might have value for predicting later adjustment, chi squares were computed between the main variables dealt with in this study and the two adjustment indices. Those included were: age, sex, presenting complaint, home status, number of siblings, physical condition, intelligence, socio-economic status, EEG findings, length of stay, diagnosis, and present living placement. The chi square tests for five of these variables were significant at the 5 per cent level or better. These were: presenting complaint, socio-economic status, intelligence, EEG findings, and present living placement. All resulted in low positive contingency coefficients which ranged between .2 and .3. These positive associations were all in the expected direction; that is, lack of presenting physical complaints, high socio-economic status, high intelligence, normal EEG, and living at home all tended to be associated with good future adjustment. Obviously, these variables are not independent and may find common ground in one or two higher order variables.

The Mental Defective Group.—The major interest in following-up the mental defectives was to

find out how many parents had taken action on our recommendations. As in the major group, we were also interested in the parents' reactions to and suggestions for the improvement of our services.

The results show that twenty-three of these children were still living in their own homes, five had been placed in state institutions, three in private institutions and the whereabouts of five was not established. Of the twenty-three living in their own homes, four were on the waiting list for admission to a state school, two were in the process of applying for state guardianship, two were on the waiting list for private institutional care. Nine families were planning to keep their children at home and six did not return or respond to this item. A plan of applying for state guardianship as a type of insurance for the retarded child, and then leaving the exact time of placement up to the parent was presented to most of this group. The results indicate moderate success was obtained in getting parents to follow the recommendations made.

The Parents' Criticisms and Suggestions.—Generally, the respondents took the opportunity of expressing their feelings and ideas about the service. Of the 177 questionnaires returned, 166 filled in this section. Ninety-nine of the respondents were motivated to write comments in addition to filling out the questionnaire. A few of these notes expressed annoyance with our persistence requesting the return of the questionnaires. Some included critical remarks about the service or the diagnosis offered. However, the large majority offered helpful suggestions.

To the question: "If you think your child has improved since he was at the hospital, what do you believe caused the improvement?", fifty-six indicated the help received at the hospital, thirty-nine believed help received from other people outside the hospital, and twenty-one felt that the child just grew out of his problems and would have regardless of the hospitalization.** The next item asked: "Have you consulted any other doctors, hospitals or clinics about your child concerning the problem for which he was seen at the University Hospitals?" Thirty-nine said, "yes," and ninety, "no," indicating that slightly more than a quarter of the respondents felt the need for an-

other opinion or more help. Better communication and rapport with the patients' parents might have reduced this "medical shopping." The last item requested the respondents to check one or more of four statements about how to improve the services rendered by the child psychiatry unit. Nineteen wished more information about what hospitalization would involve prior to admission, twenty-five indicated their need for more time with the physician, sixty-one desired more detailed explanation of the tests and studies done, and fifty-seven asked for more specific recommendations for the planning and management of the child. It seems clear that a considerable proportion felt that the service can improve its techniques in communicating the results of work done in the hospital and in offering, when possible, more specific help to the parents in managing their problem children.† The last part of this item was open-ended and solicited suggestions as to the improvement of the service. An informal tally of their suggestions generally support and reinforce the impression gained from the structured part of this item listed above.

Discussion

One of the most noteworthy aspects of the present investigation is the excellent percentage of returns and the fine interest and co-operation shown by the respondents to our questionnaire. It is felt that personalizing the cover letter, being persistent about having the questionnaires returned, and following a few simple rules of questionnaire design paid dividends.

Our findings cannot be compared exactly with any of the previous studies reported because of differences in the sample, the methods of obtaining the follow-up data, and the lengths of time since discharge or treatment. However, our results of roughly 17 per cent the same or worse, 68 per cent showing some degree of improvement, and 15 per cent unknown appear encouraging. This seems especially so when the type of population and the shortness of the hospitalization are considered. The staff has a tendency to echo the sentiments of Cohen and Carper:³

"The adjustment results shown by the present survey substantiates rather well what the clinic personnel have

**These figures are based on the 145 questionnaires returned by the major group.

†This criticism may justifiably be questioned in that some parents did not understand, accept, or remember the counsel and help offered them. However, this fact is considered a challenge for the development of better techniques.

long maintained, namely, that decidedly favorable results are obtained from the type of clinic service provided, despite its drawbacks. This is not to say, however, that the program has been entirely satisfactory. On the contrary, the clinic personnel is in full agreement that better results would have been obtained with more intensive treatment."

The attempt at developing a crude prognostic index failed. The unreliability of the ratings on adjustment made by the parents and of the child's traits as noted by the hospital staff may have attenuated any relationship which does exist between these variables.

The parents' suggestions were most helpful in stimulating the staff to review its methods and procedures and in providing a nucleus of ideas for improving the total service.

Summary

1. A questionnaire follow-up was made on the first two hundred children discharged from the inpatient service of the University of Minnesota Child Psychiatry Station.

2. The rate of questionnaire returns was high (90 per cent). The results indicate approximately 17 per cent the same or worse, 28 per cent slightly improved, 40 per cent markedly improved or well, and 15 per cent unknown.

3. Suggestions from parents indicate their need for more detailed information about their child and more specific help in planning management. Suggested also was their desire for a follow-up contact which would help them to make optimal use of the hospital experience.

A research training program to increase scientific manpower for clinical and non-clinical cancer research has been established by the National Cancer Institute of the Public Health Service, Department of Health, Education, and Welfare. Funds totaling \$1,200,000 were appropriated for the program by Congress.

Surgeon General Leroy E. Burney has approved 15 research training grants, totaling \$819,067 to 14 institutions whose applications were recommended by the National Advisory Cancer Council.

The program extends and supplements but does not replace the research training opportunities available through regular research fellowships and through employment on research projects. Under this program the institutions receiving funds select and appoint the individuals to be trained and determine the stipends they are to be paid.

Slightly more than half of the total appropriation of \$1,200,000 was earmarked by Congress especially for training in fields of chemotherapy and steroid hormones. The research fields represented among the 15 grants

are: cancer chemotherapy, steroid biochemistry, research medicine, pharmacology, biochemistry, immunology, research surgery, histochemistry, electron microscopy, genetics, cytology, radiobiology, and cancer biology.

The following grants for training in chemotherapy and steroid hormones were announced: University of Utah, \$74,145; Clark University, \$97,761; Columbia University, \$52,812; Yale University, \$37,800; Sloan-Kettering Institute for Cancer Research, \$100,000; Roswell Park Memorial Institute, \$32,616.

Other research training grants have been awarded to: University of Wisconsin, \$45,792; University of Minnesota, two grants of \$50,000 each; University of Kansas, \$38,802; Brown University, \$52,380; Stanford University, \$50,000; Washington University, \$11,577; Roscoe B. Jackson Memorial Laboratory, \$75,000; Massachusetts General Hospital, \$50,382.

Requests for information concerning this program should be addressed to the Research Grants and Fellowships Branch, National Cancer Institute, Bethesda 14, Maryland.

Historical Milestones in the Treatment of Congenital Dysplasia of the Hip

ANTHONY J. BIANCO, JR., M.D.
EINER W. JOHNSON, JR., M.D.

Rochester, Minnesota

CONGENITAL dislocation of the hip has been known and described since ancient times. Its important precursor, congenital dysplasia of the hip, however, has been recognized only since discovery of the roentgen ray. Since the existence of congenital dysplasia of the hip has been known, however, the basic concepts of diagnosis and treatment of this congenital deformity have radically changed. This brief historical review of the evolution of the treatment of congenital dislocation of the hip, and of the events leading up to recognition of congenital dysplasia of the hip, is presented with the hope that the "modern" concept of congenital dysplasia and its treatment will, as a result, appear more understandable.

The early "orthopedists" of the Indian, Egyptian, Greek and Roman cultures were too concerned with the treatment of that more socially acceptable patient, the injured warrior, to leave any worth-while records of treatment of the congenitally deformed. Orthopedics had its scientific beginning, along with the other branches of medicine and surgery, in the Hippocratic Corpus sometime between 400 B.C. and the first century A.D. Whether or not the physician Hippocrates had any actual connection with this amazing group of books, there is no doubt that it is the first medical work of any real scientific value, and while its principles were ignored or forgotten for centuries it is now recognized as the foundation of many of the modern methods of practice.

Congenital dislocation of the hip was well known and described in the time of Hippocrates. In the treatise, "On the Articulations," Hippocrates wrote: "Those persons, then, are most maimed who have experienced the dislocation *in utero*."¹ He also wrote: "There are persons who,

from birth or from disease, have dislocations outward of both the thighs; in them, then, the bones are affected in like manner, but the fleshy parts in their case lose their strength less; the legs, too,

Fig. 1. The scamnum of Hippocrates. (Reproduced with permission from: Hart, V. L.: *Congenital Dysplasia of the Hip Joint and Sequelae* [in the Newborn and Early Postnatal Life]. Springfield, Illinois: Charles C Thomas, 1952, 187 pp.)

are plump and fleshy, except that there is some deficiency at the inside, and they are plump because they have the equal use of both their legs, for in walking they totter equally to this side and that."¹ The typical gait of the patient with either unilateral or bilateral dislocations of the hip joint was further described, as well as the shortened limb, the tilted pelvis, and the tendency to bear weight on the normal side. The increase in

deformity in untreated patients was recognized and deplored.

Treatment of congenital dislocation consisted of reduction by longitudinal traction—the method

Fig. 2. Guillaume Dupuytren (1777-1835). (Reproduced with permission from: Osgood, R. B.: *The Evolution of Orthopaedic Surgery*. First Detroit Orthopaedic Lecture, Auspices of the Wayne County Medical Society, Detroit, Michigan, March 16, 1925. St. Louis: The C. V. Mosby Company, 1925, 70 pp.)

varied, however, with the age of the patient. Simple manual traction in a straight line was used in children. One method of reduction in adults consisted of suspension of the patient by his legs from an overhead beam. A strong assistant placed his arm across the patient's perineum and then swung free from a stand adding his weight to the patient's in the line of traction. The famous scamnum of Hippocrates was still more powerful, using windlasses to apply longitudinal traction. No manipulations of the joint were recorded—traction seemed to be the only method used for reduction and continued to be the only method of treatment for 2,000 years (Fig. 1).

In the early nineteenth century, congenital dislocation of the hip was still considered an incurable deformity. Use of braces and built-up shoes constituted the chief supportive measures designed to allow the patient to tolerate his

deformity. In 1826, Dupuytren² (Fig. 2), said to be the most highly trained French surgeon of his time, and characterized by Percy³ as the "first of surgeons and the least of men" because of his mean disposition, was the first to describe accurately the basic pathologic anatomy of the deformity. He wrote:

"The appearances I have found in such subjects are the following: All the muscles which have their attachments above or below the acetabulum were drawn up towards the crest of the ilium. Amongst these muscles some were well developed, whilst others were attenuated and slightly atrophied; the former were those which had preserved their action, the latter those the action of which had been cramped and limited, or even entirely negated by the altered relation of their attachments. Of the latter class some few were reduced to a sort of yellowish fibrous tissue, amid which the eye sought in vain for any trace of muscular fibre.

". . . The cotyloid cavity is either altogether absent, or presents only a small osseous, irregular prominence, where neither trace of diathrodial cartilage nor vestige of synovial or other capsule, nor fibrous margin is to be found; but which is surrounded by some tough cellular tissue, and covered by the muscles which are inserted into the smaller trochanter. Once, in two or three subjects which have been submitted for my examination, I met with the round ligament of the joint very much elongated, flattened above and, as it were, worn at certain points by pressure and friction of the head of the femur.

". . . The head of the bone itself is lodged in a hollow, somewhat analogous to that which is developed around it in accidental dislocations upward and outwards which have remained unreduced. . . ."

On the basis of necropsy findings, Dupuytren correctly concluded: "This displacement consists in a transposition of the head of the femur, from the cotyloid cavity on to the external iliac fossa (dorsum) of the ilium, a transposition which exists at birth, and which appears to be due to a defect in the depth or completeness of the acetabulum, rather than to accident or disease."

Dupuytren designed a girdle which attached to the pelvis and which supposedly exerted pressure directly on the trochanter and indirectly on the femoral head from above and laterally. While this apparatus was in favor for many years, Dupuytren's final conclusion as to treatment was that ". . . unfortunately, the deformity is incurable." However, as a result of his dissections and basic conclusions, it was not long before several methods of manual reduction were devised.

In 1835, Humbert and Jacquier² described a

method of treatment consisting of longitudinal traction with the application of lateral pressure. In 1838, Bouvier,² and in 1841, Pravaz,² reported reduction by manipulation. In 1847, Nélaton² described the line that normally passes the upper edge of the greater trochanter in running from the anterior superior iliac spine to the ischial tuberosity. Any displacement of the trochanter above this line was evidence of disease of the hip, and this line became a valuable aid in the diagnosis of congenital dislocation of the hip.

The period of these early investigations and attempts at manipulative reduction could probably be designated the "Pioneer Era" in the treatment of congenital dislocation of the hip; while the success of these methods was not remarkable by modern standards, nevertheless they stimulated further research and interest in a condition that up to then had been considered incurable.

Manipulative Reduction

In 1888, Agostino Paci,² one of the greatest orthopedists of nineteenth-century Italy, reported a method of closed reduction that depended on manual force to overcome any obstruction encountered during the manipulation. In 1894, he reported twenty-four cases in which this method of treatment was used. This was the first series of treated patients ever reported on. Upon publication of this report, both Adolph Lorenz² of Vienna and Hoffa² claimed that reduction was impossible by this method. However, only two years later, they both were advocating a method of reduction almost identical to Paci's, so that now it is Lorenz's name that is associated with the so-called bloodless method of reduction, and Paci, the true pioneer, is largely forgotten.

This method consists of flexing the affected hip of the anesthetized child until the femoral head is forced from its superior position to the posterior margin of the acetabulum. The thigh is then abducted, and with longitudinal traction applied to the leg, the leg is extended until the femoral head is levered over the posterior acetabular rim (Fig. 3). Lorenz was the first to advise subcutaneous adductor tenotomy to aid in the reduction when gentle massage of the adductor failed.

To maintain reduction, Lorenz² used plaster spica casts with the legs in 90° abduction, 90° flexion and 90° external rotation (the well-known

"frog position") for nine months. Obviously, the success of this method depended on the age of the patient when treatment was begun, yet no real attempt was made to begin treatment before the age of weight bearing.

Fig. 3. Closed method of reduction. (Reproduced with permission from: Hart, V. L.: *Congenital Dysplasia of the Hip Joint and Sequelae [in the Newborn and Early Postnatal Life]*. Springfield, Illinois: Charles C Thomas, 1952, 187 pp.)

At the Lorenz Clinic, however, the upper age limit for attempting manipulative reduction was still considered higher than at most other centers, but in most instances the method was found to be most successful in children less than three years of age. In time, however, the severe complications occasioned by the incorrect use of force during the so-called bloodless reduction caused it to be condemned and later to be replaced by adequate traction preliminary to either gentle manipulation or open operation when indicated.

Operative Methods of Reduction

Almost at the same time that manipulative methods of reduction were being developed, operative methods of correcting the deformity were being perfected. In 1835, Bouvier² recommended subcutaneous subtrochanteric osteotomy in the correction of late-stage deformity.

Pravaz² in France in 1847, and Brodhurst² in England in 1866, also recommended this procedure in older patients with marked deformity.

In 1840, Guérin² attempted tenotomy on all the muscles attached to the greater trochanter, and then planned to replace the femoral head without difficulty by simple traction. This reduction

failed since nothing was done to correct the hypoplastic acetabulum.

In 1879, Roser² resected the hip joint specifically to correct congenital dislocation. Correction

reported use of this procedure. Smith, Petersen and Lance² later improved the operation by use of bone chips above the shelf to increase the area of osteogenesis. Ghormley² was the first to use

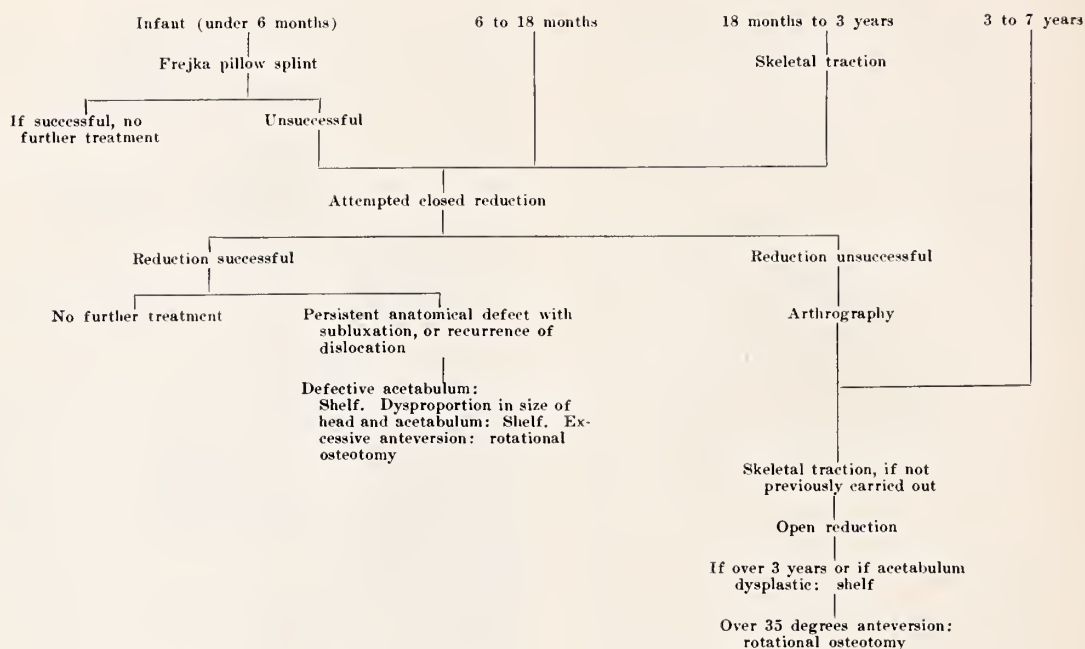

Fig. 4. Diagrammatic representation of the modern treatment of congenital dislocation of the hip. (Reproduced with permission from: Campbell, W. C.: *Campbell's Operative Orthopaedics*, Ed. 3. St. Louis: The C. V. Mosby Company, 1956, vol. 2, pp. 1105-2124).

of deformity was achieved at the expense of stability, and the operation was discarded.

The first logical operation devised for this deformity was performed by Poggi² in 1880, who was the first to take into consideration the observation of Dupuytren more than fifty years earlier that the basic deformity was due to hypoplasia of the acetabular roof, regardless of whether the femoral head was reduced or not. Poggi actually deepened the shallow acetabulum and remodeled the femoral head as necessary to complete the reduction.

In 1890, Hoffa² of Berlin adopted this operation, modified it somewhat, and advocated it widely. His name like Lorenz's gradually became associated with a procedure he did not devise.

In 1891, Koenig² used a slightly different approach to the basic pathology of the deformity and devised the first shelf operation for this condition. He described the operation as the construction of a bony "stop" or "block" for the femoral head. This consisted of a shelf turned down from the ilium just superior to the acetabular rim.

In 1904, Ferguson,² and in 1909, Jackson-Clark,²

chips from the anterior superior iliac spine and nearby iliac crest, and thereby called attention to this easily exposed source of available cancellous bone.

Albee² in 1913 devised a supra-acetabular sliding bone graft for a shelf, and in 1935 Compere² and Phemister² used a tibial graft as a shelf.

In 1918, von Bayer² recognized the fact that the chief cause of disability in many cases of congenital dislocation of long standing was the instability of the joint rather than its abnormal superior displacement. He concluded that in these cases it would be best to accept the dislocation but use the shaft of the femur as a strut for support against the acetabulum. He performed subtrochanteric osteotomy and attempted to place the proximal end of the shaft into the acetabulum. This was known as the bifurcation operation or osteotomy. Lorenz² adopted this operation in 1919 but did his osteotomy through the trochanters.

Shanz² modified the operation in 1922 because the proximal end of the shaft rarely remained in the acetabulum. He performed osteotomy well

below the lesser trochanter, and the proximal end of the shaft was placed against the ischium below the acetabulum.

Diagnostic Aids

Parallel to the development of both the closed and the open methods of treatment and equal to them in importance was the development of the various aids to diagnosis. The value of Nélaton's line in diagnosis has already been mentioned.

Development of the knowledge of x-rays discovered by Roentgen in 1895 helped to change the entire philosophy of treatment from that of treatment of dislocations as they occurred to that of early diagnosis and prophylactic treatment to prevent occurrence of dislocation.

In 1911, Shenton² described the line formed by the inferior margin of the neck of the femur and the superior margin of the obturator foramen. Its value, of course, has been in the x-ray examination of abnormal hips without actual dislocation.

Preiser⁴ in 1907 first suggested that congenital subluxation with poor adaptation between the femoral head and the acetabulum is the most common etiologic factor in the eventual development of degenerative disease of the hip.

In 1925, Hilgenreiner¹ of Prague introduced the term "congenital dysplasia" of the hip joint, which included both dislocation and subluxation. He emphasized three x-ray features of congenital dysplasia: (1) delayed development of the center of ossification of the capital femoral epiphysis, (2) increased angle of inclination of the acetabulum, and (3) lateral position of the most superior portion of the femoral neck.

In 1934, Kleinberg and Lieberman² first observed that the angle which the roof of the normal acetabulum makes with the horizontal is much less than that which occurs in a dysplastic hip. By measurement of this acetabular angle or acetabular index the possibility of dysplasia in a newborn could be predicted even before clinical examination was feasible.

Concept of Early Treatment

Another fundamental advance in the treatment of congenital dysplasia of the hip was development of the principle that the disease must be diagnosed and that treatment must be begun as soon after birth as possible.

Lorenz⁴ originally objected to early treatment mainly because of the difficulty in keeping the

child clean. He also claimed that the greater stability of the soft parts after the third year increases stability after reposition and so increases the chances for permanent reduction.

(Reproduced with permission from: Hart, V. L.: *Congenital Dysplasia of the Hip Joint and Sequelae* [in the Newborn and Early Postnatal Life]. Springfield, Illinois: Charles C Thomas, 1952, 187 pp.)

Haglund⁴ of Sweden considered the best time for treatment to be at two to three and a half years of age. Patients in whom the disease was diagnosed before that age was reached often had

Teaching Hernia Repair by McVay Technique

DONALD J. FERGUSON, M.D.
RICHARD L. VARCO, M.D.
Minneapolis, Minnesota

THE AUTHORS have a combined experience of eighteen years during which they have used and taught exclusively the McVay method for repair of inguinal and femoral hernias. This method originally recommended itself to us because of the thorough anatomic studies on which it is based, and because we are in agreement with the two surgical principles which characterize the operation: (1) *Restoration of the transversus layer* (consisting of the transversus muscle and aponeurosis, and the transversalis fascia and fascia propria fused with this aponeurosis) as the primary and natural barrier against herniation, and (2) *repair of defects in the transversus layer by transposing normal tissue into them without tension*. The operation has been thoroughly and clearly described.^{1-3, 8-12}

Although the analysis of scientifically conducted follow-up studies at present available does not give a conclusive answer to the problem of recurrent hernias, sufficient data are at hand to indicate that in this respect the McVay operation is at least as good a choice as any.^{4,12} The authors are further influenced by the fact that though not all patients have been followed, they have yet to encounter a recurrence in any patient they have operated upon or assisted a resident to operate on by the McVay technique. This statement may well bring a smile to anyone who knows the pathetic fallacies of hernia follow-up statistics; our more intelligent patients, for one thing, if they have had a recurrence, doubtless tried their luck elsewhere.

Nevertheless, during the same period of time, we have each encountered repeated instances of recurrent hernia in patients operated upon by surgical trainees whom we are partly responsible for teaching, and who state that they were employing the McVay operation. We are chastened, moreover, by this evidence that our teaching of the procedure has not been successful. Probably both more teaching time by us at the operating

table and more specific didactic emphasis is needed.

In our efforts to remedy this situation we have analyzed the mistakes discovered when re-operating upon patients with recurrent hernia, where the original repair was said to be a McVay operation. Some of these errors are common to any type of hernia repair; others are peculiar to the McVay operation.

Extirpation of the Sacs

Failure to find all the peritoneal sac or sacs present in the inguinal-femoral region is a classic mistake, easily avoided yet frequently committed. It is a simple matter to open the peritoneum near the internal ring, whether or not an indirect hernia appears to be present, and to explore digitally from inside, the triangle of Hesselbach, the femoral ring, the obturator ring, and the internal abdominal ring, where an indirect sac may have been overlooked. Except in infants, this exploration should be routine. The older the patient, the likelier he is to have more than one sac. Even in infants, femoral hernias may be present along with the common indirect hernias, but the incidence seems to us sufficiently low so that exploration is unnecessary, and the required enlargement of the tiny peritoneal defect is perhaps unwarranted. Often the sacs in direct or femoral hernia can be pulled up and excised as part of the same defect used for exploration. The opening should be carefully closed with interrupted silk, flush with the parietal peritoneum. It may be added, however, that while there is abundant evidence that failure to remove completely a sac predisposes to recurrence, there is little evidence that failure to close the peritoneal edges is of any more importance here than it is after extensive abdominal operations for cancer, in which large areas of peritoneum are removed without subsequent herniation. The primary barrier against herniation is the transversus layer, and the importance of the sac lies in its capacity to keep open a defect in

¹Presented before the Saint Paul Surgical Society, February 15, 1956.

that layer. When all sacs are removed, the McVay technique provides fascial covering for all actual or potential inguinal-femoral hernia sites.

Defects Along Cooper's Ligament

The McVay operation requires suture of the lower free edge of the transversus layer, obtained by excision of all attenuated tissue surrounding the hernia, to Cooper's ligament, from the pubic tubercle to the femoral vein. We have encountered failures in this suture line at both ends and in the middle. The apparent causes of breakdown have been (1) an inadequate number of sutures, (2) failure to carry the suture line far enough in each direction, (3) interposition of extraperitoneal fat between stitches, and (4) excessive tension through failure to provide an adequate relaxing incision.

The optimum spacing of sutures has been worked out experimentally for fascial layers,⁵ and, as a general rule, the maximum tensile strength may be anticipated when stitches are taken 5 mm. apart and 5 mm. from the edge of a free fascial layer in which the large fibers run parallel with the edge. Only small bites are necessary in the dense tissue of the superior pubic ligament. In hernia repair the sutures certainly ought not to be further apart than 5 mm., and seven or eight of them are usually required for this approximation along the length of Cooper's ligament. Silk of size 3-0 or 2-0 is satisfactory. The suture line should begin right at the pubic tubercle. Both the free edge of the transversus layer and the entire extent of Cooper's ligament to be used in the repair should be carefully freed of all fat and areolar tissue by sharp dissection and finally by rubbing with dry gauze. This step will promote firm healing of the fascia.⁶ Great care should be taken that the peritoneal fat does not protrude between sutures as they are tied. This fat should likewise be painstakingly dissected from the area next to the femoral vein.

The lateral extent of this suture line is a crucial matter, and perhaps the commonest mistake we have found is failure to carry it far enough to close the femoral ring. The last stitch laterally should be behind the medial part of the femoral vein, but in the narrow type of pelvis it may be more conveniently taken in the pectineal fascia instead of Cooper's ligament. This is the deepest and one of the more difficult parts of the operation. The vein need never be injured if a finger is always interposed between it and the needle.

The vein should be clearly seen and should not be appreciably compressed when sutures are tied. Its sheath should not be removed as it helps to seal the ring. Spacing of the sutures along the transversus layer must be judged so that there is no lateral tension along this layer when the sutures are tied down on the rigid structure of Cooper's ligament. The vertical tension is determined ultimately by the length of the relaxing incision, which extends vertically near the midline for a distance of about 3 to 6 cm. upward from the symphysis pubis, through the inner two layers of the rectus sheath. This vertical tension is also determined at the time of operation, however, by the degree of relaxation produced under anesthesia, and it is not easy to obtain the optimum condition. When relaxation is complete there should be no appreciable tension. If the anesthesia is minimal and the patient restless, tension should not be greater at the suture line than elsewhere in the abdominal wall. We believe that the relaxing incision should never be omitted, otherwise we forego a principal advantage of this operation by forcibly stretching tissue out instead of sliding it over in normal condition.

The suture line in the transversus layer is continued up over the femoral sheath toward the internal ring. The sheath is frail, and sutures here can only serve to seal the vein against the transversus fascial edge, which is firmly held in place by the sutures in Cooper's ligament and the pectineal fascia. When favorably located, the stumps of the divided inferior epigastric vessels provide a good anchor for sutures. We have not observed any recurrence in this area except when the suturing to Cooper's ligament has been defective.

The Abdominal Ring

The internal inguinal ring is an opening in the transversus layer, and is not readily accessible from the outside. Surgeons are prone to attempt closure of this ring around the cord by suturing the transversus layer previously freed up medially, or even the more superficial internal oblique muscle, to the inguinal ligament. As students of anatomy realize, such a closure is a centimeter or more away from the real ring, and therefore does not close it. This area is a common site of recurrence with most types of repair. Proper closure can be difficult, but is attainable. The transversus layer on the lateral side of the ring composes the sheath over the external iliac artery, which is readily palpable.

The sheath is thicker than that over the femoral vein, and holds sutures well. It is usually obscured by fat, however. The ring should be closed so tightly that it slightly compresses the cord, and the fingertip cannot enter it. Postoperative swelling of the cord and testicle is not likely to occur as a consequence of tight closure of the ring. It is usually the result of blunt dissection of the cord, with damage to veins and lymphatics. Only sharp dissection with the scalpel should be used in separating the cord from the sac and surrounding tissues. Finally, the cord should be fastened to the internal ring with a few small "tacking" sutures so that it cannot slide in and out, perhaps pulling with it a wedge of fat or peritoneum.

Weakness of Tissues

We have seen recurrences directly through the transposed part of the transversus layer used to cover the original defect. This layer is normally not very thick, but is in the form of an intact, close-meshed sheet of collagen fibers. In some individuals, however, the layer is infiltrated with fat, and displays gross separations of the aponeurotic fibers. When in that condition it must be reinforced. The simplest expedient is to include the external oblique aponeurosis when making the relaxing incision, and to slide it down and suture it with the transversus layer to Cooper's ligament. The rectus muscle protects the resulting defect. An external ring is formed with Scarpa's fascia and the inguinal ligament. Where suitably aponeurotic, the internal oblique may be included with the transversus. An alternative is to turn down a flap of external oblique aponeurosis.⁷ Rarely is it necessary to use a free fascia lata graft for reinforcement or replacement of part of the transversus layer. This latter method is successful when properly used, and we therefore have not found it necessary to try dermal grafts, metal screening, or other such devices.

Preparation of the Patient and Postoperative Care

Several of the recurrences which we have seen have been in patients who had a chronic cough, obesity, or both. Other studies have shown the importance of these items in the genesis of wound complications. We believe that no elective surgery should be done until these conditions have been corrected. Abdominal distention and constipation can also be sources of stress on the healing wound and they should be prevented. If the colon is

cleansed before surgery and mineral oil by mouth provided liberally in the postoperative period, these events are usually avoidable. Retching or vomiting are likely to be especially damaging. We have observed our sutures being broken or pulled out when this occurred on the operating table. With general anesthesia, nasogastric suction should always be used; with local or spinal anesthesia, inhalation of oxygen is often helpful in preventing nausea and retching.

Any increased stress of this sort should be avoided for three weeks, and heavy exertion should be prohibited for three weeks more. After that, full activity should be resumed gradually without any permanent restriction.

No Necessity for Recurrence

Such are the sources of recurrent hernia in our experience with the McVay operation. We wish to emphasize that these are preventable. The fact is, recurrence of a hernia indicates the surgeon failed to do his best operation. Nearly every operator is perfectly willing to try another procedure on a patient who comes back with a bulging repair, thereby tacitly admitting the truth that something better should have been done the first time. A surgeon may remark that if a hernia repair of his breaks down, the only recourse will be to do a graft or transplant, implying that everything possible has been done with the tissues available in the area. On the contrary, this is seldom the case, and it is only necessary to carry out the McVay procedure exactly as it was originally described, in order to cure the patient. In a few instances, the tissues may have been defective, but here also the corrective measure should have been undertaken at the first operation.

Bleeding from the Genitourinary Tract

With Emphasis on Traumatic Injuries

OLIVER E. SARFF, M.D.

Duluth, Minnesota

HEMATURIA is simply defined as gross or microscopic blood in the urine and must always be considered an alarming symptom. All too frequently it is painless and intermittent in character. As a result some type of therapy often is instituted before the origin of the bleeding has been properly investigated. Bleeding is prone to cease with or without therapy after twenty-four to seventy-two hours. As a result, there is a tendency, both on the part of the patient and the physician to minimize the condition. This frequently leads to serious miscalculations in diagnosis with resultant disaster to the patient. Even though the hematuria may have ceased by the time the patient presents himself, the physician must always complete a thorough urologic investigation to determine, if possible, the source of the blood. Kretchmer¹ in reviewing 932 cases of hematuria, stated that the average duration between the first evidence of hematuria and diagnosis showed an elapsed time of about two and one-third years. This corresponds with a series of 1,600 cases reviewed by Dr. Charles Higgins² of the Cleveland Clinic in which the elapsed time between the initial bleeding and diagnosis was over two and one-half years. Dr. Edwin Davis³ of Omaha reported 1,000 consecutive cases of hematuria and classified his series as follows: 303 were seen in the first week, 233 cases during the next three weeks, 193 from one to five months, 85 from six to eleven months, 71 from eleven to eighteen months and 115 were not seen until eighteen months had elapsed. This record is better than those of the two authors previously mentioned, yet is still far from desirable. It is obvious that earlier diagnosis and initiation of definitive therapy is necessary if a satisfactory result is to be gained. Dr. Davis noted that 782 of the 1000 cases were caused by serious organic lesions involving the urinary tract. An additional 85 were diagnosed as cases of essential hematuria. In the

remainder, the bloody urine was caused by minor diseases which nevertheless needed definitive treatment. Doss⁴ reviewed nearly 6,000 cases of hematuria and found that inflammatory lesions, neoplasms, foreign bodies, tuberculosis and trauma were the most frequently found and in that order. Thus, it is apparent that hematuria is a most serious symptom and deserves immediate attention. My own records reveal 81 per cent of the patients with bladder tumors presented themselves with painless hematuria. One can conclude that approximately 80 per cent of all cases of hematuria are due to serious organic lesions.

The question of essential or idiopathic hematuria is one of the most perplexing situations encountered in the field of urology. Recently much has been written about lesions which cannot be demonstrated either through direct vision or by pyelography, but for which bleeding was sufficiently severe to warrant nephrectomy. Nation, Butts, and Massey⁵ described a lesion involving the entire kidney which they believed to be on an allergic basis and which presents a definite histologic picture. They feel that many of the cases of chronic hemorrhagic papillitis and purpuras belong to this group. It is my belief that true essential hematuria is rare indeed. If such patients are followed closely, the origin of the bleeding usually will become apparent.

Before investigating suspected cases, it is important to establish the presence of blood in the urine. A number of drugs such as aspirin and urotropine cause hematuria. Ingested red beets commonly discolor the urine. Two simple ways in which the presence of blood in the urine may be established are (1) microscopic examination of the urinary sediment and (2) the Meyer's test. The latter is a very simple but sensitive test for minute amounts of blood in the urine. It is performed by adding one cubic centimeter of Meyer's reagent to two cubic centimeters of urine and overlaying it with hydrogen peroxide. A purple color between the layers is indicative of the pres-

Presented at the annual meeting of the Minnesota State Medical Association, Minneapolis, May, 1955.

ence of blood. It is surprising how little blood is necessary in the urine to produce grossly recognizable hematuria.

Certain clinical features of hematuria are helpful in determining the source. Initial hematuria suggests bleeding from the urethra distal to the external sphincter; terminal hematuria often means the patient is bleeding from the prostate or bladder; in the event of total gross hematuria one simply does not know the source without the use of x-ray or cystoscopy. "Fish worm clots" usually are formed in the ureter. When blood is well mixed with urine and does not clear up with irrigations, the source of bleeding usually is in the bladder. If irrigations do clear the urine, bleeding must have come from the upper urinary tract. There are other signs and symptoms which may help to indicate the source of bleeding. Clots passing through the ureter produce pain on the affected side and may simulate the passage of calculi. Flank pain with a palpable mass would suggest the kidney as a source of hematuria. As I previously stated, in painless hematuria a bladder tumor should be considered until disproved. These are all diagnostic clues, but a final opinion must be obtained through intravenous pyelography, cystoscopy and retrograde studies.

The sources of hematuria may be divided into three general classes: (1) Those concerned with diseases in the urinary tract itself (intrinsic); (2) those arising from neighboring viscera (extrinsic); and (3) hematuria associated with general disease. The possible causes of hematuria within the kidney include: trauma, neoplasms, stones, infections, congenital anomalies, polycystic disease, solitary cysts and nephritis. There are many others, and all are possibilities. Benign prostatic hypertrophy is more apt to cause bleeding than carcinoma. Within the bladder, bleeding is much more often caused from neoplasms, stone, tuberculosis, trauma and infection. In the urethra, stricture and trauma are the most commonly found etiologic factors. Appendicitis, pelvic infection, pelvic neoplasm, and diverticulitis are the most common offenders among extrinsic causes.

A discussion of hematuria due to injuries to the urinary tract will be covered in somewhat greater detail than the other causes of blood in the urine. Trauma of the upper urinary tract is not an uncommon finding and may be classified as follows: (1) Simple contusion with subcapsular hemorrhage; (2) minor parenchymal lacerations,

with or without capsular involvement; and (3) complete rupture of the entire organ involving the capsule, pelvis, and sometimes even the vascular pedicle, which is often rapidly fatal.

Anatomically, the normal kidney is well protected and injuries are usually confined to simple contusion or minimal parenchymal tears. More severe trauma is usually associated with penetrating wounds (stab or gun shot) or coexisting with complicated skeletal and visceral injuries. Severe damage can more easily result from acts of minor violence to a previously diseased kidney (hydro-nephrosis, cystic disease, neoplasms, et cetera) and evidence of a kidney traumatized out of proportion to the inciting injury should always excite suspicion of pre-existent renal pathology. Symptoms naturally will vary widely, according to the extent and number of associated injuries. It is well to keep in mind at all times that profound damage can be present and yet be well masked by associated complicating injuries, such as ruptured liver or spleen. Bleeding usually is mild and transitory with simple contusion and usually only moderate pain and tenderness are present. In the more severe parenchymal lacerations, pain and tenderness with a palpable mass in the flank, profuse hematuria, together with abdominal distention and shock, are the most commonly found symptoms. Early and precise information is imperative if conservative treatment is to be accomplished. No examination of a severely injured patient is complete without a routine examination of the urine, and if at all possible, a catheter should be passed into the bladder. If bloody urine is found the patient should have the benefit of an intravenous pyelogram as quickly as is compatible with his general condition. Even though the affected side reveals no function, the procedure can establish the presence of a normal opposite kidney, information which may be invaluable in the event that emergency surgery becomes indicated. It is my feeling that retrograde study usually is necessary for intelligent diagnosis and proper treatment. If, because of the patient's general conditions or lack of facilities, this cannot be accomplished, he should be watched very carefully. I have seen a number of patients admitted with minimal hematuria which cleared after several days, but which was followed after several weeks with an almost fatal hemorrhage. Fortunately, most injuries can be watched and treated expectantly with a high degree of success. Sar-

gent⁶ reported 206 cases of kidney trauma observed on the urologic service at the Milwaukee County General Hospital. He classified 120 as simple contusion (all of which needed no surgery), seventy-two as major parenchymal damage but comparatively normal pelvic architecture, and fourteen as a completely shattered kidney. In the group with major lacerations but intact pelvises, only two required immediate surgery. Of the remaining, only nine who were followed very carefully over a long period of time were subjected to surgical procedures for complications which developed later, including perinephritic abscess, atrophic kidney, Goldblatt's syndrome and the like. There were no deaths in this group. Of the fourteen cases of shattered kidney, six were diagnosed at autopsy. Nephrectomy was performed immediately in six more patients, and the other two were operated upon in conjunction with abdominal procedures for visceral injuries, both dying during the long surgical exploration. Procedures will vary according to the damage. These range from immediate nephrectomy after shock control, to drainage of extravasated blood with repair of the kidney. The kidney has a remarkable power of recuperation if given the opportunity through close observation and conservative treatment with the exercise of good judgment.

Injury to the lower urinary tract usually concerns itself with rupture of the bladder and/or urethra. The tear in the bladder may be extraperitoneal or intraperitoneal and may result from penetrating spicules of bone following a fracture of the pelvic bones. On the other hand, the rupture may be due to a direct blow over a full urinary bladder and is explosive in character. An empty bladder usually escapes injury even with crushing injuries to the bony pelvis. Symptoms vary according to location and the amount of damage. If the intraperitoneal extravasation of urine is present, symptoms of peritoneal irritation and ileus will soon make their appearance. They are often accompanied by varying degrees of shock. Pain and tenderness in the suprapubic area are present. The patient may be found to be dribbling or passing bloody urine. An early attempt should be made to catheterize the bladder, but this procedure should be discontinued if it is not accomplished with ease. If successful, a cystogram with a radiopaque agent should give one valuable information. The use of irrigating fluids

and measurements of the amount returned is mentioned only to condemn it, as it has been entirely inadequate. If indicated, repair of the bladder with abdominal exploration should be carried out as quickly as possible, with the object of draining the bladder and the prevesicle and retroperitoneal spaces.

Urethral trauma is usually the result of fracture of the pelvic bones, or a direct blow to the urethra such as occurs in straddle injuries. An important anatomic structure to keep in mind is the urogenital diaphragm. Rupture proximal to this organ results in extravasation to the spaces above, limited by the periprostatic and perivesicle fascial cleavage planes. In all cases of hematuria and, certainly, whenever the diagnosis of pelvic fracture is established, an attempt to catheterize the bladder should be made as quickly as possible. If any resistance is met, it should be discontinued. Since such injuries are all proximal to the urogenital diaphragm, the surgical approach should be suprapubic and with bladder an perivesicle space drainage. A catheter may then be passed retrograde through the urethra and a Foley catheter permitted to remain indwelling in the bladder. Urethral injuries distal to the external sphincter may vary widely according to the extent of damage. A slight, but constant, urethral bleeding is usually noted, and if seen early, and the damage is moderate, a catheter frequently can be passed into the bladder and left indwelling. On the first examination, there may be no evidence of extravasation to the perineum, but some hours later it may be found that there is swelling with ecchymosis and tenderness; perineal drainage should then be instituted as quickly as can be arranged. In the more severe injuries or in complete ruptures, the patient usually has retention with exquisite pain in the perineum and suprapubic area with marked swelling, tenderness, and discoloration of the perineal area. If some time has elapsed, the extravasation may be extended up over the abdomen before the patient is first examined. Usually a catheter cannot be passed by that time and the perineum should be drained as promptly as the patient can be brought to surgery. When the urethra is exposed, the clots are removed and the extravasated area is drained widely. A catheter frequently can be passed into the bladder through an external urethrotomy and left indwelling. If the ruptured urethra can be repaired it is well to do this promptly, but, if the patient's condition

Fig. 1.

Fig. 2.

Fig. 3.

does not warrant excessive surgery, secondary repair can be made when the patient's improvement permits. If the catheter cannot be passed or the patient cannot be moved, suprapubic cystotomy should be done at once with drainage. Varying degrees of stricture formation follow urethral injuries, and strict attention to their dilatation periodically must be followed, if the patient is to obtain and retain a good result. If the patient's condition is so critical that nothing can be accomplished initially, side tracking of the urine by simple trochar cystotomy will suffice temporarily, with secondary drainage of the perineum and repair of the urethra as quickly as can be done with safety.

The following case reports are illustrative of the conditions mentioned:

Case Reports

Case 1.—An elderly man, (C. J. T.), aged seventy-six, was admitted to the hospital December 14, 1952, complaining of hematuria with pain in the left flank, with some burning and smarting on urination, following an injury forty-eight hours previously. He had been struck over the left kidney and over the lower left chest by a large boulder falling from a truck. He was taken care of at the local infirmary and hospitalized overnight, during which time he was treated for mild shock. He had some difficulty in breathing, which was probably due to a fractured rib. He continued to have total gross hematuria and was admitted to my service for further study. He had had no difficulty with his urinary tract since having a transurethral resection for benign prostatic hypertrophy with complete retention in 1950. The rest of his history was not remarkable. His only complaint was tenderness over the left kidney and in the left lower chest with considerable muscle guard-

ing, but no palpable mass could be felt. The rest of his examination was essentially negative.

An intravenous pyelogram taken elsewhere had revealed a normal appearing right kidney, and a non-functioning left kidney. Therefore, on December 15, the day after admission, a retrograde study was done. The bladder was normal in appearance with blood seen coming from the left ureter. Catheters were passed up to both kidneys without meeting obstruction. Urine was obtained and sent for culture. The left kidney was filled by the gravity method and the roentgenogram disclosed opaque material apparently scattered throughout the minor calyces and parenchyma, suggesting a lacerated kidney (Fig. 1). The calyces were not well visualized. There was no extravasation beyond the capsule. The patient was therefore treated conservatively, and a transfusion of 500 cc. of whole blood was given. The hemoglobin was 61 per cent on admission and 71 per cent following the transfusion. A Foley catheter was left indwelling, although the patient was voiding well. Hematuria ceased after eight days. The catheter was then removed and the patient voided clear urine without difficulty. He was kept in the hospital for two more days of observation and sent home as ambulant but ordered not to work.

The patient returned January 23, 1953. Another retrograde study was made (Fig. 2), and marked improvement of the left kidney was evident. He was discharged to go back to his work, and recent follow up reveals that he is asymptomatic.

Case 2.—A nineteen-year-old boy was admitted to the hospital December 13, 1953 in shock following an automobile accident. He had sustained an injury over the right flank, followed by extreme pain and gross hematuria. He was watched for two days by the attending physician, during which time he continued having marked hematuria and increasing pain and ileus. He was given two transfusions. Because of a marked increase of the hematuria on December 16, I first saw

Fig. 4.

Fig. 5.

Fig. 6.

the patient in consultation. There was a large palpable tender mass in the right flank with associated distention of the abdomen. The bowel sounds were normal. A cystoscopy was performed, and it was noted that clear urine effluxed from the left side. Indigo carmine appeared in moderately good concentration in six minutes. On the right side, there was a constant flow of blood from the ureter. A catheter was passed up the right ureter and a pyelogram study was made (Fig. 3). Figure 4 shows a pyelogram of the left kidney revealing a congenital type of hydronephrosis with a definite stricture. An exploratory operation, performed the same afternoon because of uncontrollable bleeding, revealed the right kidney to be a badly ruptured hydronephrotic sac. In addition, there was considerable bleeding from a renal vein which had been torn. The kidney was removed.

Several weeks later, a left pyeloplasty with nephrostomy was done. The nephrostomy tube was left indwelling because the patient's azotemia failed to respond despite the nephrostomy drainage. However, he felt greatly improved despite his high blood urea, and he was discharged from the hospital with the nephrostomy tube in place some eight weeks later. A creatinine of 4.5 mg. per cent and blood urea nitrogen between 50 to 6 mg. per cent continued despite the plastic procedure on the left kidney and adequate drainage. He gradually lost strength and expired with symptoms of uremia the following September, eight and one-half months after injury.

Case 3.—A fifteen-year-old boy was admitted to the hospital March 18, 1955. In a scuffle, he had sustained a mild injury to the right ilio-costal space from the elbow of a boy companion, which caused no distress or pain at the time. The boy went to a restaurant, had lunch, and upon retiring at home at one o'clock noticed that he was passing bright red blood. By the next morning the bleeding had become more profuse and he was admitted to my service about four o'clock in the after-

noon. An immediate intravenous pyelogram was made which can be seen in Figure 5. One sees the shadow of an enlarged left kidney, which is normal in contour and architecture; on the right side, however, there is severe dilatation of the calyces, and the pelvis does not fill with media. This gives the impression of being a large hydronephrotic kidney.

The patient was treated expectantly because of profuse bleeding, and after thirty-six hours of conservative care with no abatement of the bleeding and after receiving three transfusions, he was taken to cystoscopy on March 21 where a retrograde pyelogram was made (Fig. 6). Nephrectomy was accomplished that afternoon. The pelvis was filled with 1500 cc. of old blood. A pre-existing pathologic condition was suspected before the patient's admission because of the minor type of injury.

Case 4.—A nine-year-old boy was admitted to the hospital March 13, 1954, following a straddle injury resulting from a fall on a fence rail. The boy voided well although a small mass was felt in the perineum. Because he was voiding without much difficulty, nothing further was done until I was asked to see him twelve days following the injury. At this time, there was a large indurated mass in the perineum, with discoloration. An extensive drainage of the perineum was accomplished surgically with additional drainage of the scrotum. An elliptical defect of the bulbous urethra was noted and a catheter was passed without difficulty past this defect into the bladder. It was felt that the indwelling catheter would allow satisfactory healing of the urethra in time and therefore no suprapubic cystostomy was done at this time. After removal of the perineal and scrotal drains, the wound healed well. The patient inadvertently pulled the catheter out, and on April 6 a suprapubic cystostomy was performed with the retrograde passing of the catheter into the bladder, which was left again for splinting purposes. The photograph of the x-ray picture shows the healing of the

Fig. 7.

Fig. 8.

Fig. 9.

urethral defect (Fig. 7). The suprapubic catheter was finally removed May 28, some two months later, and there was no extravasation of dye in the urethra. The patient was voiding well with clear urine.

He was readmitted in September, 1954, at which time the urethra was calibrated by passing catheters and found to be entirely adequate. Cystoscopy revealed a normal bladder. It has not been necessary to dilate the urethra of this patient as frequently as usual. After another six months, the urethra was again calibrated and found to be entirely satisfactory.

Case 5.—A sixty-eight-year-old man was admitted to the hospital September 16, 1954, following a straddle injury to the perineum. There was considerable bleeding from the urethra and an accumulation of blood and urine in the perineum. The patient was taken to the operating room where perineal drainage was accomplished, and a rupture of the urethra was identified. A catheter was easily passed into the bladder. One suture was taken in the urethral tear and the perineal wound was closed about two Penrose drains. Following removal of the drains, the perineum healed without any further difficulty. The catheter was left indwelling as a splint. Four weeks later the catheter was removed and the patient was able to void in very small amounts. The calibration procedure disclosed that a twenty-four sound could be passed with ease. A check revealed 300 to 350 cc. of residual urine on several occasions. As a result of a cystoscopy examination, he was found to have a benign prostatic hypertrophy with marked trabeculation of the bladder, cellule formations, and one opening to a large diverticulum (Fig. 8). Following transurethral removal of the prostate, the patient voided 200 to 300 cc.'s at a time but still carried a large residual, amounting to 150 to 200 cc. On one occasion I checked his residual immediately after voiding, and found 15 cc., but ten minutes later I found 120 cc. In my opinion, adequate resection had been accomplished, and therefore diverticulectomy was performed. Following this, the patient has been able to void and empty his bladder well. His urethra has been dilated at six week intervals and its calibre remains adequate. (Fig. 9.) Cystourethrogram reveals an increased calibre of the urethral stricture and the definite improvement of the bladder following the removal of the large diverticulum.

Case 6.—J. B. H., aged twenty-five, was admitted to the hospital May 30, 1947, after being struck by a truck. He was first seen in the emergency room in shock, with fractures of the right tibia, left clavicle, right ulna and the ninth, tenth and twelfth left ribs. It was also noted that he had a moderate hematuria. The patient's condition improved following symptomatic treatment and the fractures were taken care of by an orthopedic surgeon. The hematuria ceased spontaneously after the third hospital day. His condition remained good until June 19, three weeks after his injury, when it was noted by the nurse at 5 p.m. that he was passing profuse amounts of blood and clots in the urine. Shortly after this, I was asked to see the patient, who by that time was in shock with greyish white pallor, rapid pulse, and a blood pressure of 80 over 60 mm. of mercury. Transfusion was started immediately, and he was taken to the cystoscopy room where a size 16 cystoscope was passed without anesthesia. Clear urine was seen to efflux from the right ureteral orifice, and there was a continuous and profuse flow of blood from the left ureteral orifice. Indigo carmine was recovered in good concentration from the right kidney in three minutes. Repeated attempts to make a pyelogram failed, for as fast as the catheters could be changed they became plugged with clotted blood.

The patient's state of shock became worse, so he was taken to the operating room immediately. He was rapidly prepared for surgery, and with little regard for surgical technique, nephrectomy was accomplished as rapidly as possible. Once the kidney was visualized, profuse bleeding was encountered and, to borrow a phrase from the late Dr. Artie Law, "Gentlemen, the hemorrhage was simply wicked." The kidney was completely covered by organized blood clots, but with sharp and blunt dissection the kidney was freed and pedicle clamps applied. Seven units of blood were given during the procedure. Following this, the patient's condition immediately improved. The blood pressure had become imperceptible but returned after a few minutes. The kidney was removed without further difficulty. Examination of the kidney revealed a laceration which extended from the hilus to the convex surface, practically bisecting the kidney. It was interesting to note that this

Diagnosis and Office Treatment of Sinusitis

JOHN C. LILLIE, M.D.
Rochester, Minnesota

SINUSITIS may be defined as inflammation of the mucous membrane of the paranasal sinuses. In recent years, the approach to the problems of diagnosis and treatment has changed and review of some of the basic concepts seems justified.

Defense

Primary.—The first line of defense of the nose against infection consists of the combination of the mucous blanket, the ciliary stream and lysozyme lying on an intact ciliated epithelium. Control of this mechanism is basically autonomic, and autonomic disturbances have been shown to disturb its defensive ability. Wolff and co-workers¹ have shown the deleterious effects of emotional and stress-provoking stimuli on this protective apparatus. Chilling of parts of the body disturbs the mechanism; ischemia, drying and change to an alkaline pH result, together with inhibition of lysozyme. Similar disturbances in surface defense, either general or localized, may be results of the following: (1) dietary or alcoholic excesses, (2) nutritional deficiencies, (3) anatomic deviations producing dry spots or severe obstruction, (4) endocrine abnormalities, (5) use of some drugs, (6) severe systemic disease, (7) too low atmospheric humidity, and (8) intranasal medication.

The last needs amplification. Alkaline medication destroys lysozyme. Irritating substances may stop ciliary motion or kill the epithelium. Oily substances may render the mucous blanket too viscid to move. Potent vasoconstrictors may upset the delicate vasomotor control. Allergic disorders produce edema and disturbance of mucosal drainage.

The foregoing consideration is not exhaustive. Other factors also may affect surface defense and

thus interfere with removal of the products of infection of the nasal sinuses.

Secondary.—If the surface defense fails, the stroma prepared for its role by the epithelial infection becomes the defense organ. The protection is provided by leukocytes, antibodies, histiocytes and other agents from the blood called to the stroma in the acute inflammatory reaction. If this defense is adequate, the infection is resolved in two or three days. If it fails, or if secondary bacterial invasion overwhelms it, then acute sinusitis of variable severity follows. The stroma continues to be the defensive tissue until healing occurs or the defense is overwhelmed and the condition becomes chronic, or the infection spreads beyond it.

Modes of Infection

Infection may reach the sinuses in ways other than by direct continuity from the nose: (1) It may be secondary to swimming, diving and sudden changes in barometric pressure; (2) infections about the teeth may involve the maxillary sinus, and the oral contamination that occasionally follows extraction of teeth may extend into this same sinus; (3) infection may follow contusion or perforation of a sinus; (4) vigorous nasal packing sometimes causes infection of a sinus; and (5) the Proetz type of displacement therapy may induce sinusal infection.

A common factor in these modes of infection is that the sinus is grossly contaminated and injured at a time when the stroma has not been prepared for it by a preceding inflammatory reaction, such as attends acute coryza. Consequently, suppuration and necrosis usually are more extensive than otherwise they would be.

Several factors tend to promote continuing, recurrent infection or spread of infection. The most important of them is impairment of drainage, which may be due to narrowing of the drainage paths from whatever cause or to failure of the ciliary stream to function. Other factors include: (1) virulence of infection; (2) lowered resistance

Dr. Lillie is in the Section of Otolaryngology and Rhinology, Mayo Clinic and Mayo Foundation.
The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

of the host; (3) constant reinfection from adjacent sinuses, the lower part of the respiratory tract, and persistent dental infection, and (4) improper treatment.

Causative Organisms

The precursors of sinusitis are the virus or viruses of acute coryza. The microorganisms usually found in cases of sinusitis include pneumococci, streptococci, staphylococci, *Hemophilus influenzae* and bacteria of the genus *Klebsiella*. If the maxillary sinus has become infected because of dental extraction or dental abscess, mixtures of oral organisms are found. When closed cavities are infected, anaerobic organisms, usually anaerobic streptococci, may be isolated. In recent years, accompanying the promiscuous use of antibiotics, infections with Gram-negative organisms, especially chronic infections, are occurring in increasing numbers. To know the type of organism present is important when sulfonamides and antibiotics are used in treatment.

Tissue Changes

The epithelium may become thickened or papillary; it may change to a stratified squamous or polypoid type. As has been said, furthermore, after infection has occurred, the stroma becomes the site of defense and it undergoes definite pathologic changes. In the presence of acute disease, the inflammatory reaction is acute and proliferation predominates. Consequently, the stroma is thick, occasionally twenty to thirty times thicker than normal, and adjacent bone may undergo proliferative change.

Symptoms and Signs

Sinusitis may be classified in five groups: (1) fulminating, (2) acute suppurative, (3) subacute and recurring suppurative, (4) chronic suppurative, and (5) chronic nonsuppurative and mixed (hyperplastic). The first three groups may be considered as acute types of sinusitis and the last two as chronic types.

The symptoms of acute sinusitis include fever, malaise, headache, a sensation of fullness of the head, nasal stuffiness or obstruction, mucopurulent or purulent nasal discharge, postnasal discharge, cough, sore throat, anosmia and pain. The pain of sinal disease tends to be local: that related to the maxillary sinuses, in the cheeks, teeth and often the supraorbital regions; that related to frontal sinuses, in the frontal or temporal regions;

that of ethmoid disease, in the region between and behind the eyes and in the supraorbital region, and that of sphenoid sinusitis deep in the head, behind the eyes and occasionally in the occiput or vertex. The pain usually results from the pressure of infection in a closed cavity or from edema involving nerve endings near the sinal ostia. Pain of sinusitis often is intermittent, may follow a daily pattern as in the "union" headache, and usually is aggravated by coughing, stooping and straining. Pain of sinusitis occurs most commonly with acute infections, including acute exacerbations of chronic disease. The pain, fever and malaise usually decrease with the onset of drainage. Tenderness over the infected sinus is of frequent occurrence. When a frontal sinus is concerned, tenderness is felt over the floor and anterior wall. When infection is of the maxillary sinus, tenderness is in the canine fossa. The medial orbital wall is the site of tenderness in the presence of infection of the anterior ethmoid cells. Occasionally, depending on the sinus infected, the eyelids, frontal region and cheek may be edematous.

Usually the nasal mucosa is red and swollen, especially in the region of drainage of the sinuses involved. Likewise, purulent secretion may be seen in these regions of drainage, which are the anterior middle meatus for the frontal and maxillary sinuses and the anterior ethmoid cells; the superior meatus and spheno-ethmoid recess for the posterior ethmoid cells and the sphenoid sinuses. Care must be taken in the interpretation of this finding, as mistakes are very possible. In general, as the process subsides the discharge becomes thicker and then of reduced quantity; moreover, most of the symptoms lessen. In the chronic types of sinusitis, the general symptoms are much less pronounced than in the acute types. Williams² has pointed out why the headache usually complained of by patients with chronic nonsuppurative sinusitis is due not to the sinal disease but to the accompanying allergic or pathergic disorder. Fatigue and mental dullness are of common occurrence. Nasal obstruction may be present, occasionally with anosmia, but the predominant significant symptom is mucopurulent to purulent postnasal discharge. Other symptoms may include chronic cough, irritated throat, hoarseness, and nasal odors. Of the many other symptoms ascribed to chronic sinusitis, most if not all are considered coincidental. Findings on

examination are minimal except for discharge and frequently associated other abnormalities, such as polypoid changes and edema.

Diagnosis

The diagnosis of sinusitis depends on the history, inspection of the nose, roentgenologic examination and the results of lavage of the affected sinus. Both anterior and posterior rhinoscopy should be performed. Irrigation of the ethmoid cells is not feasible, nor it is often feasible when the frontal or sphenoid sinuses require treatment; suction, following shrinkage and cleansing, however, frequently discloses the source of the secretion. Roentgenograms seldom are needed in diagnosis of obvious acute sinusitis, but they are of great value in establishing the presence of chronic sinusitis. Pattee³ compared the relative value of several procedures used in the diagnosis of chronic maxillary sinusitis and concluded that: (1) roentgenograms, nasal examination, and the history were of value in that order in focusing attention on the maxillary sinus as the source of disease; and (2) lavage was by far the best means of determining the activity of the disease. Other methods used for diagnosis are transillumination, antroscopy, cytologic studies, bacterial cultures, contrast roentgenograms and planograms, biopsy, studies of the blood, allergic surveys, and so on.

Treatment

Present treatment of sinusitis is the result of improved understanding of the subjects just covered. Methods of today contrast with those in use following the discovery of cocaine in 1885 when radical treatment was guided by the concepts of free drainage (the more the better) and of removal of all diseased tissue. For example, epithelial changes were considered irreversible and the affected tissue was removed. The present trend is toward conservatism and restoration of a physiologic situation.

General treatment consists of supportive and antibacterial measures.

As general supportive measures, analgesics and sedatives are administered, and dietary measures, rest, quiet, avoidance of chilling and avoidance of overindulgences are prescribed. These measures are useful primarily in the acute types of sinusitis and should be employed as freely as necessary.

Antibacterial measures include administration of sulfonamides, antibiotics, vaccines and serums. Topical use of sulfonamides and antibiotics has

proved unsatisfactory. On the other hand, in cases of acute sinusitis, systemic use of these agents has decreased both the necessity for surgical measures and the morbidity, and has controlled most of the complications. Use of the agents named, however, in no way obviates the need for adequate drainage. It is probably advisable in most cases, if not in all of them, to obtain cultures and to study the sensitivity of the isolated microorganisms to the action of therapeutic preparations; then the agent to which the organism is most susceptible can be used. In the interval before the reports of results of cultures and sensitivity studies have been received, a combination of penicillin and streptomycin may be administered to combat one or more of a rather wide variety of possible invaders. It is important to use enough of a preparation, long enough, to kill an infecting organism rather than to enhance its resistance to the therapeutic substance. Most writers on the subject have expressed the belief that these agents should be given only after the appearance of pus, not during the coryzal stage of acute sinusitis, and that they accomplish nothing against chronic sinusitis. Vaccines and serums are useful occasionally in treatment of chronic suppurative sinusitis and in allergic cases.

Drainage-promoting measures remain the *sine qua non* of treatment in cases of sinusitis. Most authors have written that a diseased sinus will not heal unless drainage is obtained, regardless of what other measures are used. In acute sinusitis the early, severe edema and epithelial damage interfere with drainage. In two or three days, however, drainage probably will be obtained through the mucociliary mechanism. In many instances all that is necessary to help this natural mechanism is to avoid further injury to it. For this reason moist, warm air and an adequate intake of fluid are helpful. Avoidance of drugs that induce drying and of intranasal medication that injures the mucociliary system furthers this aim. Some of these injurious agents are menthol, camphor, alkaline and sulfonamide solutions, antiseptics, oily substances and strong solutions of cocaine. Prolonged douching also is injurious. When the head is semi-erect, gravity helps drainage. Tobacco and alcohol tend to increase swelling and are better avoided.

A controversial subject is that of vasoconstrictors which are used to provide temporary relief of nasal obstruction and to increase ostial drainage.

Fabricant⁴ stated that the ideal agent had not been found because all in use had a secondary, "rebound" effect, probably from the fatigue of the vasoconstrictor muscle fibers. This fatigue results in a period of mucosal swelling after the power of the vasoconstricting agents has been dissipated. For this reason, many rhinologists deprecate the use of vasoconstrictors or suggest sparing use of only moderately potent drugs. Of these, the best are thought to be 1 to 2 per cent solution of ephedrine hydrochloride and 0.25 to 0.5 per cent solution of phenylephrine (neosynephrine) hydrochloride, both applied topically. These are believed to do little injury to the nasal tissue but still to retain some effectiveness. The controversy over the use of vasoconstrictors goes on.

The preceding measures, or some of them, are usually sufficient in the early stages of the acute sinusitis. After seven to ten days, if drainage still is inadequate, irrigations by cannula or displacement treatments usually are instituted. In addition, minor surgical procedures, such as infraction of the middle concha, may be used to open constricted channels of drainage. Generally, manipulations and cannulations are ill-advised early in the disease, as they confer little benefit and invite spread of infection. Lavage of a sinus also is not without some dangers, one of which is formation of air embolism.

Many physicians employ displacement treatment, but again dangers exist, one of which is that the solution tends to enter and contaminate uninvolved sinuses and the eustachian tube. The Dowling pack provides slow decongestion with no "rebound"; this, followed by gentle suction, works well, but is condemned by some persons as being irritating and a ciliary inhibitor. Use of hot compresses, infrared lamps and diathermy gives much subjective relief and encourages drainage. Heat is best used after the early edematous stage; if heat is used in the course of the edematous stage, it can aggravate the pain.

After active infection has subsided, for chronic types of sinusitis surgical measures to facilitate drainage may be indicated. Although minor procedures, irrigation of the maxillary sinuses, displacement, and use of Dowling packs are effective at times, promotion of drainage in the presence of chronic disease of the nasal sinuses is primarily a surgical problem.

Anti-allergic measures are important, especially for chronic, nonsuppurative disease, but also for

mixed chronic sinusitis. These include hypsensitization, use of antihistamines and vasodilator drugs, avoidance of offending allergens and other control of the environment, although change of climate is of questionable value.

Prophylactic measures are many and varied, and include any and all means which improve drainage and effect the strengthening of the two defense systems, epithelial and stromal.

Roentgen therapy, especially for acute frontal sinusitis, has significantly helped in alleviating pain. In 70 per cent of a series of cases compiled by Popp and Williams,⁵ it brought about earlier resolution than otherwise would have been expected.

Special Problems.—A few special problems in treatment arise in certain situations. Fulminating sinusitis, of which swimming is a predisposing cause, is usually a closed-cavity infection; hence, there is no drainage and a situation favorable to the growth of anaerobic microorganisms is present. The stroma is involved before any inflammatory defense has been set up. Severe prostration, pain and serious threat of spread are characteristics. Use of potent analgesics, of vasoconstrictors, of antibiotics effective against a sufficiently wide variety of microorganisms, and heat are indicated. It is generally thought that without obvious evidence of improvement within twelve to twenty-four hours, and certainly with evidence of increasing infection, drainage should be obtained at once by surgical means. The maxim of early conservatism does not hold in this situation. The frontal sinus is usually the one involved.

About 10 per cent of acute maxillary sinusitis is of dental origin. It is uncommon among children. The acute maxillary type is another massive infection of an unprepared stroma and usually has severe effect upon the mucous membrane. Unilateral location, foul odor, and severe systemic symptoms are typical. Drainage must be helped by vigorous means, and broadly effective antibiotics should be used. Failure of early resolution usually indicates that surgical drainage will be needed.

Obstructive arosinusitis is produced by sudden barotrauma, usually an increase in the atmospheric pressure while the ostium is occluded as by a polyp or inflammatory swelling. The resulting relative negative pressure in the sinus produces stromal damage and hematoma. This process may

subside without infection; but if infection does occur, the disease will be severe—again because of the unpreparedness of the stroma — and vigorous treatment is in order. Sinusitis from fractures and other trauma will behave in very much the same fashion as this type.

Sinusitis of specific cause such as tuberculosis, actinomycosis, rhinoscleroma, and so on, is rare. The treatment is that of the infection present.

Children.—Sinusitis of children differs somewhat from that of adults. Antral and ethmoid disease is possible from birth, and frontal and sphenoid disease becomes possible at from four to seven years of age. Infection of sinuses of children is probably more common than is realized. Systemic reactions and local cellulitis afflict children more frequently than adults, the maxillary and ethmoid sinuses being those usually involved. Ethmoiditis is accompanied by orbital complications more frequently among children than among adults. Subacute and chronic sinusitis of children are commonly manifested by frequent colds, runny nose, stuffy nose, chronic cough, and recurrent sore throat. There may be recurrent otitis, apathy and fevers. Anosmia leads to anorexia. The diagnosis and treatment do not differ from those for adults, but the methods are not so easy to apply. Pulmonary complications are common in children with chronic types of sinusitis, and adenoidal disease may promote chronicity.

Complications

The incidence of complications of sinusitis has been greatly reduced by the use of antibiotics, as well as by more conservative early treatment—so much so that serious complications are now unusual. Complications of sinusitis may be classified as follows:

1. Spread by mucosal continuity
 - (a) Nose (acute sinusitis in other sinuses, acute rhinitis)
 - (b) Nasopharynx (nasopharyngitis, otitis media, mastoiditis)
 - (c) Pharynx and larynx (pharyngitis, tonsillitis, laryngitis)
 - (d) Lower part of respiratory tract (tracheitis, bronchitis, pneumonia, bronchiectasis)
 - (e) Eye (conjunctivitis, dacryocystitis)
2. Spread by vascular, lymphatic or direct extension
 - (a) Orbit (edema, cellulitis, abscess)
 - (b) Facial soft tissues (cellulitis or abscess of cheek, forehead and adjacent soft tissues)

- (c) Facial and cranial bones (osteitis, osteomyelitis, fistulas to surface, dura or mouth)
- (d) Cranial cavity and its contents (meningitis, subdural empyema, extradural abscess, brain abscess, venous sinus thrombosis)
- (e) Septicemia or metastatic abscess in a part other than the head

3. Others

- (a) Focal infection
- (b) Mucocoele and pyocoele

Spread by mucosal continuity is still of common occurrence and may occur in the course of any stage of sinusitis. Faulty nose blowing, misdirected early treatment (such as displacement treatment and nasal douching) and virulent infections tend to increase the incidence of the complications listed in Group 1. Their diagnosis and treatment are the same as for any of their causes, with proper management of the sinus disease added.

The more serious but fortunately now rare complications of sinusitis are those listed in Group 2. Spread occurs most commonly by venous emboli and by way of veins that are sites of periphlebitis and thrombophlebitis, often of retrograde type. Lymphatic structures play a role in bringing infection to perivenous tissues. Lymphatic spread can take place via the perineural spaces of the olfactory nerves to the subarachnoid space and thence to the orbit and face. Spread may also occur by extension from sinuses in the bony walls of which are defects that may be congenital, traumatic, operative or disease-produced. Spread of ethmoiditis to the orbit is commonly by such a route, but spread from the ethmoid sinus may occur in any direction. The complication depends on the location of spread. Osteomyelitis occurs mostly in the frontal bones, rarely in others. Among intracranial complications, 45 to 60 per cent used to be postoperative; but these now are rare, thanks to prophylactic use of antibiotics in conjunction with surgical treatment of the sinuses. Meningitis is the most common complication in the cranium at present. The various entities present signs and symptoms no different from those of the same diseases arising from other causes, and their nonsurgical treatment is also similar. Two points are important, though. When these complications result from sinus disease, the sinus must be drained at once or as soon as local resistance and antibiotics have controlled the spread of infection. The widespread use of antibiotics for minor respiratory illnesses

has resulted in so obscuring the spread of sinusitis that at times silent or unexpected complications occur.

Mucocele and pyocele are complications which are primarily surgical in management.

Comment

Important studies of sinusitis have been concerned with the etiology, pathogenesis, physiology and defense mechanisms, both surface and stromal. From these studies have come present-day concepts of nonsurgical treatment, which may be expressed in these generalizations:

1. Sinus health is based on an intact functional mucous membrane and free drainage.

2. Identification and control of some of the many factors that disturb normal mechanisms have assumed increased importance.

3. Treatment is aimed at restoring structure and function to normal, not at removing structures to the destruction of function.

4. Adequate drainage remains the keystone of treatment.

5. Antibiotics are potent new weapons against sinusitis, especially against the acute disease and complications.

6. Chronic sinus disease is still too often not appreciably aided by nonsurgical measures and remains a challenge to the rhinologist.

CONGENITAL DYSPLASIA OF THE HIP

(Continued from Page 11)

to wait for treatment. Ridlon⁴ also expressed the belief that treatment should be started only after the age of weight bearing.

In 1939, Putti⁵ made the greatest contribution to the modern treatment of this disease; he reported a cure rate of 94 per cent in children in whom the condition was recognized at a very early age and who then were treated by the abduction method. He emphasized that it is important to educate parents and physicians in the early recognition of the condition and in the necessity for beginning treatment immediately. He stated: ". . . Therefore one must reduce the age limit, *indeed abolish it completely*, and fully accept that principle, which all orthopaedic surgeons follow in the treatment of all congenital deformities, and which one sees no reason to repudiate in that of congenital dislocation of the hip—that is, to *begin treatment the very moment the deformity is observed*, even if that be on the day of birth."

Modern Methods of Treatment

To attempt even to enumerate the many

methods of treatment of congenital dysplasia and dislocation of the hip in use today would be far beyond the scope of this article. However, it seems worth while to show diagrammatically the possible steps in the present management of this condition as influenced by the age of the patient when the diagnosis is established. This is done in Figures 4 and 5.

Psittacosis in Minnesota

A Review of the Last Ten Cases Seen at University of Minnesota Hospitals

WILLIAM R. FIFER, M.D.
Minneapolis, Minnesota

THE RECORD of psittacosis apparently dates to 1879, when a Swiss bird fancier, following receipt of a collection of parrots, noted a severe respiratory illness among seven members of his household which was fatal to three.⁸ Parenthetically, the parrots fared no better. It required fifteen years for Morange to identify the parrot as the vector of this malady, and he named it psittacosis. (Gr. Psittakos-Parrot)¹⁵

Serious thought was directed at the disease after the great epidemic of 1929-30 which involved some 800 persons in twelve countries, with a 20 per cent mortality.³ Since the pandemic appeared to have begun in Argentina and then spread to North America, England and Europe, many countries of the world imposed a strict embargo on the shipment of psittacine birds which resulted in a gratifying rarity of the disease until 1951 (Table I). At this time, the embargo was lifted because sufficient evidence was available to show that other than psittacine birds were an important reservoir of the disease, and that effective antibiotics were at hand. Since the embargo-lifting, however, an alarming increase in reported cases has occurred, and one may assume that reporting is far from perfect. This reappearance of the disease, which has awakened the interest of the medical profession, is due to the lifting of the embargo on psittacine birds and to their booming popularity as household pets.

The malady is rare in children (only 5 per cent of the cases in most series occur in persons under age fourteen),¹⁰ and has a varied clinical spectrum. Most patients complain of malaise, chills, fever, a dry cough, severe headache, myalgia and pleuritic pain. In our group of cases (Table II) fever was accompanied by shaking chills in five patients. The cough was more often dry than productive, and tended to be "irritative," causing

paroxysms of cough. Headache was a prominent symptom, and at least two of the cases were initially considered to have acute sinusitis because of the severity of the headache. The fever, chills,

myalgia and malaise with dry cough most often suggested the diagnosis of "flu," and the presence of pneumonia was not suspected until roentgenograms disclosed a pulmonary infiltrate. The onset of the disease may be gradual or abrupt, usually follows an incubation period of about ten days.³ Symptoms subside in two to three weeks, although

From the Department of Medicine, University of Minnesota Hospitals.
Presented at the meeting of the Minnesota Society of Internal Medicine, May 12, 1956.

many persons remain ill for months (Case 1) and relapses have been noted.

Physical examination may be completely unrewarding, as early in the course of the disease the pneumonia is interstitial, and hence silent. Later, rales may appear, and an enlarged, soft spleen may be noted. Occasionally a skin rash may be seen, simulating the rose spots of typhoid fever.¹⁵

The leukocyte count ranges from five to ten thousand and chest roentgenogram may disclose an area of pneumonitis which has been variously described as "ground glass" or "fluffy opacification."³ As seen in Table III, our cases ranged in age from nineteen to sixty-three years, and were rather evenly divided with respect to sex. The source of infection was a parakeet in five instances, was undetermined in three instances, and was clearly related to non-psittacine birds in two cases. The chest x-rays of all patients disclosed a definite area of pneumonia, except for one which the radiologist described as bilateral pulmonary congestion.

The etiologic agent is a large virus which, in psittacine birds, is named *Miyagawanella psittacii*. *M. ornithosis*, the virus in non-psittacine birds, is in the same antigenic family, as is the virus of lymphogranuloma venereum. The terms "psittacosis" and "ornithosis" are used, respectively, to designate disease arising from contact with psittacine and non-psittacine birds. The virus, lodged in the spleen of affected birds, may or may not cause illness in the bird, and most sick birds undoubtedly recover spontaneously. The virus is passed from one bird generation to the next, thus perpetuating the reservoir. It is not known whether this familial propagation is accomplished by egg-borne infection or by direct passage from parent to baby in the nest. Certainly, most humans acquire their infection from parakeets, either by airborne dessicated bird droppings, handling sick or dead birds, or contact with nasal discharge, feathers, or excreta, as when cleaning the cage.³ The list of birds other than the parakeet which act as disease reservoirs include the cockatoo, cockateel, kea, lorikeet, lory, lovebird, macaw, and parrot; and among the non-psittacine birds, the pigeon, duck, chicken, turkey, finch, gull, pheasant,⁴ dove, canary, and fulmar.² There have also been documented instances of transmission from human to human,^{6,10} and Meyer and Eddie reported a case of a human carrier who harbored the virus for ten years.¹⁴

TABLE III. CLINICAL PSITTACOSIS

Case	Age	Sex	Source of Infection	WBC (1,000/cu.mm)	Area of Pneumonia
1. HK	57	M	Parakeet	5.9—17.4	RUL

8. HM	47	M	Pheasant	9.7	LLL
9. LC	38	F	?	7.2	Bilat.
10. VS	19	F	Parakeet	5.5	RUL

One of the most interesting features of the transmission is the great variation of human susceptibility to the disease. Some patients acquire serious infections after only fleeting contact with the offending bird, while a member of the household who has been in prolonged and intimate contact with the same bird remains well, and may not even develop a significant antibody rise. However, the high incidence of complement-fixing antibodies in modest titres in the serum of bird-lovers suggests that subclinical infection is common.³

The serologic diagnosis of the disease merits special comment. First, the problem of cross-reaction with the virus of lymphogranuloma venereum is a problem in areas where the venereal infection is prevalent.¹ False positive reactions have also been seen in Q fever and brucellosis.^{5,10} In Case 1, a Q fever titre of 1:64 occurred as a cross-reaction to a psittacosis titre of 1:256. Because of the close antigenic relationship of psittacosis and lymphogranuloma viruses, and because of the prevalence of low titre antibodies in bird lovers, it is generally agreed that proof of clinical illness should rest on: (1) isolation of the virus during the acute illness (this has been accomplished from sputum, blood, and throat washings of human cases),¹⁰ or (2) a four-fold or greater increase in complement-fixing antibodies. Many authors, however, consider a titre of 1:32 in association with a typical clinical illness as ample presumptive proof of the disease. It should be noted that in our Case 2, positive proof of the disease was obtained by isolation of the virus from the family parakeet, even though the titre of antibodies never exceeded 1:32. Finally, it may be noted that a closely related virus causes sporadic encephalomyelitis in cattle.^{11,13} The patient in our Case 1 had a cow with antibodies against this virus. There is no evidence that cattle act as a reservoir of the disease in this country, however.

TABLE V. RECOVERY OF VIRUS FROM BIRD

1. Saline suspension of ground bird spleen and liver
2. Inoculate mice
3. After 7 days, kill 2 mice and examine liver and spleen for exudate. If (+) grind organs and make suspension
4. Second passage intracerebrally and intraperitoneally. If virus present these mice become ill on 3rd or 4th day. They are killed and impression smears are made of spleen and brain
5. Machiavello's or Castaneda's stain examined for elementary bodies
6. Third passage is done if necessary

Since the antibody titre may not develop until ten to thirty-five days after the onset of the disease,⁸ one must decide on the basis of clinical grounds whether to treat the patient as psittacosis. This is an extremely important practical point, especially since there is evidence that the disease can be effectively treated by the tetracycline family of antibiotics. Tetracycline itself seems to be most effective,⁹ and since it appears that prompt therapy may actually suppress the development of antibodies,³ one may ruin his serologic diagnosis by his therapy. The serology of the reported cases is shown in Table IV. All cases included in this report had psittacosis CF titres of 1:32 or greater. The long persistence of antibodies despite adequate chemotherapy is illustrated by Case 1, whose titre was still positive 1:64, 115 days after the onset of the illness. On the other hand, the mild case of psittacosis in Case 2, which was promptly treated, produced only a transient rise of antibody titre which returned to negative thirty-two days after the onset of the disease.

Our group of cases supports the idea that tetracycline offers very effective therapy and is probably the drug of choice. Figure 1 illustrates the rapid lysis of fever by tetracycline (within three days) in two patients treated by this drug alone. It also shows the persistence of fever for five days in one case, despite adequate penicillin therapy, with prompt lysis when tetracycline was instituted.

What other means of proof of the disease exists? We would like to stress the usefulness of isolation of the virus from the parakeet. This is accomplished by injecting bird spleen hemogenate into the peritoneum of the white mouse followed by

Fig. 1.

a second passage intracerebrally and thence demonstration of the elementary bodies (Table V). The Minnesota State Board of Health Laboratories accomplished this isolation in three of fifteen suspected parakeets during 1955.

Case Reports

Case 1. (UH #889177).—H. K., a fifty-seven-year-old white farmer became ill Sept. 22, 1955, with a "flu" syndrome followed in a week by dry cough, shaking chills and fever. The illness did not respond to penicillin and chest x-ray showed an atelectatic pneumonia in the right upper lobe. After eighteen days, bronchoscopy and a right bronchogram were done because of the suspicion of bronchogenic carcinoma, and he was referred to University Hospitals. Because of the atypical course of the infection, psittacosis complement fixation test was performed and was positive in a dilution of 1:512. The patient then recalled, on direct questioning, brief exposure to a cage of parakeets at a county fair about two weeks before he became ill.

This patient has had a severe and prolonged debilitating illness, which has now lasted six months, with evidence of liver damage (CCF 4+, serum A/G—3.1/3.8) and protracted weakness, malaise, diaphoresis and chronic cough. His titre was still positive in a dilution of 1:64 on the 110th day of the disease.

Case 2. (UH #800499).—L. H., a thirty-one-year-old white physician's wife became ill February 23, 1956, with shaking chills, temperature 105° F, a dry cough, headache, myalgia and right pleuritic chest pain. Chest x-ray showed a pneumonitis in the right upper lobe. Her husband had purchased a parakeet six weeks prior

to the illness as a birthday present for their daughter. The bird was always healthy, but the virus was recovered from this bird. The patient was treated with tetracycline and was afebrile in three days. She was well in one week. The maximum titre was 1:32 on March 9, and antibodies had disappeared by March 22, 1956.

Case 3. (UH #867819).—N. G., a sixty-year-old white milkman became ill in February, 1954, with the "flu" characterized by a dry cough, anorexia, temperature up to 102.4° F., and right lateral pleuritic chest pain. Chest x-ray showed pneumonitis in the right upper lobe. A history was obtained that he frequented a bar which contained a decorative cage of parakeets just above the patrons' heads. His psittacosis CF test was positive in a titre of 1:64 on March 12, 1954. Recovery occurred concomitant with tetracycline therapy.

Case 4. (UH #863721).—W. R., a sixty-three-year-old white man noted left pleuritic pain, October 15, 1953, associated with fever, nonproductive cough, malaise and arthralgia. Questioning about his occupation disclosed that he dressed rabbits, ducks, pheasants, chickens, geese and deer. He had cut his hands many times on sharp bones, and one cut on this thumb became badly infected and had to be "lanced" by a physician three days before he became ill. Axillary, inguinal and cervical lymph nodes were enlarged and tender, and a friction rub was heard over the left anterior hemithorax. The psittacosis CF test was positive at a dilution of 1:128. A roentgenogram showed pneumonia with atelectasis in the left lower lobe. The patient remained afebrile and symptoms abated over a six day period without therapy. He was lost to follow-up.

Case 5. (UH #893227).—G. F., a forty-nine-year-old white man became ill January 8, 1956, with headache, malaise, chills and minimal cough which was productive of small amounts of brownish sputum. He had bought a parakeet in December, 1955. Chest x-ray showed pneumonitis in the lingula of the left upper lobe. He became afebrile in twenty-four hours on tetracycline therapy and roentgenographic evidence of pneumonitis cleared within two weeks. The psittacosis CF test was positive at a dilution of 1:32.

Case 6. (UH #862838).—D. T., a twenty-five-year-old white woman noted fever and generalized arthralgia which was treated with aspirin with a clinical diagnosis of rheumatic fever in July, 1953. On August 23, 1953, she developed a temperature of 104° with inflammation of the right knee and ankle associated with cough, photophobia, "red spots" on legs and pain in the right upper anterior chest. The leukocyte count was 8,350 per cu. mm., and the cold agglutinin and C-reactive protein tests were negative. The muco protein measured 5.8 mg per cent. The psittacosis CF was positive at a dilution of 1:512 and the antistreptolysin-O titre was 400 Todd units. Chest roentgenogram showed pneumonitis in the right lower lobe. She was treated as having both rheumatic fever and psittacosis and made a slow recovery. No history of exposure to a parakeet was obtained.

Case 7. (#885644).—M. D., a fifty-four-year-old white man developed a temperature as high as 104° F., headache, weakness and malaise on June 6, 1955. He was treated with penicillin with some clinical response, but fever recurred on June 20, 1955. He was afebrile on admission on July 1, 1955. Chest roentgenogram showed only peribronchial "congestion" bilaterally. No bird history could be obtained. The psittacosis titre was positive at a dilution of 1:32.

Case 8. (UH #893357).—H. M., a forty-seven-year-old white man became ill on December 28, 1955, with a temperature of 101°, headache, malaise, cough and myalgia. He was not benefitted by penicillin, and a chest roentgenogram made January 2, 1956, showed pneumonitis with pleural reaction in the left mid-lung field. The psittacosis CF test was positive at a dilution of 1:64. After questioning, he recalled that his son had recently caught a pheasant in a trap and brought the bird home to keep in the basement. He had a good clinical response to treatment with tetracycline.

Case 9. (UH #891097).—L. C., a thirty-eight-year-old white woman was found acutely ill with a severe bilateral pneumonia November 18, 1955, associated with a temperature of 105° F and mental confusion. The fever responded somewhat to penicillin and streptomycin therapy. The cold agglutinin reaction was positive at a dilution of 1:28. The psittacosis CF was positive at a titre of 1:32. Serial chest roentgenograms showed gradual clearing of the bilateral fluffy pneumonia accompanied by lysis of the fever after tetracycline therapy was begun. No history of exposure to birds was obtained.

Case 10. (SHS #14330).—A nineteen-year-old white girl, V. S., complained of chills, fever, and headache December 10, 1955. Her illness was clinically diagnosed as "sinusitis" and she was treated with penicillin with some response. On February 3, 1956, she developed a nonproductive cough, malaise, chills and fever and recurrence of the frontal headache. Chest x-ray showed an "infiltrate" in the right upper lobe and the psittacosis complement fixation test was positive at a titre of 1:64. This patient was exposed to parakeets in South America six months before this illness and had a protracted "bronchitis" at that time. There was no known exposure to parakeets since.

Summary and Conclusions

The clinical aspects of infection with the psittacosis virus have been reviewed in the light of ten recent cases seen at the University of Minnesota Hospitals. This study emphasizes:

1. The sharply rising curve of incidence of this preventable disease concurrent with the unregulated shipment and sale of parakeets.
2. The extreme variability of both susceptibility to and infection with psittacosis virus, ranging

(Continued on Page 42)

Case Presentation

Acute Subdural Empyema of Otic Origin

ALFRED UIHLEIN, M.D.

Rochester, Minnesota

ACUTE subdural empyema arises from a fulminating intracranial infection and ends fatally unless it is recognized early and treated promptly by surgical means.¹⁻⁵ The infection frequently arises in the paranasal sinuses, whence it spreads through septic thrombophlebitis^{6,7} to involve the epidural space, and then by direct extension penetrates to the subdural space⁸ and spreads rapidly over the convexity of the hemisphere without entering the subarachnoid space.^{9,10} The subdural collection of pus may either localize over the hemispheric convexity or penetrate the interhemispheric fissure, or do both.¹¹ Since the introduction of antibiotics, the condition fortunately has become rare; but its clinical pattern is encountered frequently enough so that the possibility of subdural empyema must be considered whenever a patient with a history of ear, nose, or throat infection suddenly becomes critically ill.

The patients usually are young adults or adolescents. The causative organisms are commonly anaerobic Streptococci or Staphylococci. The source of the infection is most often a nasal sinus and on rare occasions, the ear.³ An instance of subdural empyema that affected a middle-aged woman and was produced by a pneumococcal infection from an otic source seemed unusual enough to justify the preparation of this report of diagnosis and treatment.

The classic pattern of subdural empyema begins with an infection of a nasal sinus or middle ear that may or may not have been adequately treated. After the infection has been quiescent for a period, the patient suddenly complains of headache, drowsiness, and stiff neck, evidences a cloudy sensorium, and lapses into semicoma. Lo-

calizing signs or the source of the infection may or may not be discoverable at this stage. The rapid deterioration of the patient's condition usually is evidence against a diagnosis of brain abscess. Within hours either Jacksonian or grand mal convulsions develop with hemiparesis of the extremities contralateral to the lesion. A pupil may become dilated and fixed. The patient suffers from fever, leukocytosis, and, if the lesion is on the left side, aphasia. A spinal tap will reveal increased pressure, increased concentration of protein, and pleocytosis to the extent of 1,000 to 2,500 cells (mostly polymorphonuclear leukocytes) per cubic millimeter of spinal fluid. The cell count is lower than in meningitis. The values for sugar and chlorides in the spinal fluid are generally within normal limits.

Because of the rapidly deepening coma, stiff neck, and convulsions, surgical treatment is necessary. Some physicians advocate multiple trephinations of the skull with aspiration of the fluid and irrigation of the subdural space,³ while others consider craniotomy more satisfactory.^{4,12} Antibiotics are given generously during the post-operative period, as well as anticonvulsants, if indicated.

Many patients recover with little neurologic sequelae, while others may have permanent defects of the visual fields, hemiparesis, and, with left-sided subdural lesions, varying degrees of sensory or motor aphasia. Recovery is dramatic, and is especially swift among younger patients.

Report of Case

A white, single woman, fifty-eight years old, was in apparent good health until mid-February, 1956. On the nineteenth, however, she called her physician to her home and stated that five days earlier she had begun to suffer from an ache in the left ear and mild fever. She had treated herself with aspirin and nose drops but had not obtained relief. The day before she consulted her physician the left ear had begun to drain purulent fluid. On the same day that she first consulted her physician she was admitted directly to a local

Read at the Southern Minnesota Medical Association, New Ulm, Minnesota, September 10, 1956.

Dr. Uihlein is in the Section of Neurologic Surgery, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

hospital because of nausea and vomiting which seemed to be projectile.

Physical examination at that time revealed a well-nourished, well-developed woman who was somewhat delirious and incoherent in her speech. She had con-

hours. Results of urinalysis were negative; the leukocyte count was 15,200 per cubic millimeter of blood, and the sedimentation rate 126 mm. per hour (Westergren method).

Shortly after admission to her local hospital, the

Fig. 1 (left). Posteroanterior ventriculogram showing shift of ventricular system from left to right. Air in subdural space on left.

Fig. 2 (right). Anteroposterior ventriculogram showing less displacement in posterior part of head by the mass on the left side.

siderable difficulty in completing a spoken sentence and had some loss of memory. The pupils were round and equal, and reacted to light and in accommodation. The nasopharynx was covered with a purulent exudate, under which the mucosa was red. Examination of the right ear disclosed nothing abnormal; the left aural canal was filled with bloodstained purulent material which came from a posterosuperior perforation in the drum. The mastoids were not swollen or tender, and the neck showed no rigidity. The blood pressure was 180 mm. of mercury systolic and 74 diastolic. Findings of the remainder of the physical examination and the neurologic examination were essentially negative. The patient's temperature on admission was 102.4° F.; by evening it had risen to 104.2°, and the following morning it was 103.2°.

At this point the consulting physician was asked to see the patient. He remarked the slurring of speech that had been noted the day before. Also, by this time definite ptosis of the left upper lid had developed, and the left pupil was dilated and did not respond to light or in accommodation. There was a rigidity, grade 4+ (on a grading basis of 1 to 4), of the neck. Hyperreflexia was generalized and Babinski's response was positive bilaterally. Spinal tap revealed that pressure had risen to 260 mm. of water, and the fluid was slightly cloudy with 1,300 leukocytes per cubic millimeter, of which 218 were lymphocytes. The value for total protein was 368 mg. per 100 cc., for chlorides 850 mg. and for sugar 180 mg. per 100 cc. Cultures of the spinal fluid showed no growth within forty-eight

patient was started on a course of 1,000,000 units of penicillin per day with 1 gm. of streptomycin four times a day; and treatment with sulfadiazine was initiated with a dose of 60 grains (4 gm.), and continued with doses of 15 grains (1 gm.) every 4 hours thereafter. Fluids were administered parenterally, and meperidine hydrochloride (Demerol) was given to control pain. By the fourth day of hospitalization, the patient had become lethargic but would respond to questioning. By the fifth day she appeared more alert and talked coherently. Nuchal rigidity was less. Cultures of the purulent material from the left aural canal disclosed *Staphylococcus albus*, and the sensitivity was highest to erythromycin; therefore, the patient was given 250 mg. of Ilotycin every four hours. Fluid from another spinal tap was similar to that obtained before, and revealed pneumococci on direct smear. The dose of penicillin was then increased to 1,000,000 units every four hours and the dose of Ilotycin to 500 mg. every four hours. By February 25 the patient seemed more lethargic and required constant nursing care because of right-sided Jacksonian seizures. A third spinal puncture revealed pressure of 580 mm. of water and cloudiness in the fluid. On the morning of February 26, the patient was found to have a flaccid paralysis of the right arm with generalized muscular twitching which was partially controlled by sedation. On the afternoon of that day she became comatose and was transferred to the Mayo Clinic with a tentative diagnosis of brain abscess.

When the patient was admitted to the hospital in Rochester she was found to have a temperature of

100° F., and a leukocyte count of 12,000 per cubic millimeter of blood. She was stuporous to comatose. Additional signs noted were stiffness, grade 4, of the neck, right hemiplegia with bilateral extensor plantar response of the lower extremities, and partial third

ment in moving the right half of the body, in taking nourishment and in carrying out the acts of elimination. She was finally dismissed from the clinic, April 3, 1956, and was cared for in a hospital near her home from April 3 to 20.

Fig. 3 (*left*). View at operation; pus was overlying brain in subdural space on left.
Fig. 4 (*right*). Left cerebral hemisphere after pus had been removed.

nerve palsy on the left. But there was no measurable papilledema, and the roentgenographic appearance of the skull was normal, with no pineal shadow. Embolic hemorrhages were noted in both eyes, which resembled those frequently seen in the fundi of patients with subacute bacterial endocarditis. Cultures of the blood made at the time of admission failed to grow any organisms, but a course of medication comprised of penicillin, erythromycin, dihydrostreptomycin and sulfadiazine was instituted immediately because pneumococci had been cultured from the spinal fluid previously. After a brief period of observation, a ventriculogram was made. It revealed a huge shift of the entire ventricular system from left to right caused by a left-sided frontoparietal space-occupying mass (Figs. 1 and 2). The fluid in the ventricles was slightly clouded and under marked pressure. Craniotomy was carried out immediately on February 27, and a huge membranous subdural empyema which covered the frontoparietotemporal area of the brain was encountered (Fig. 3). The subdural empyema was completely removed (Fig. 4); because of cerebral edema the bone flap was removed also, and because of the patient's critical condition an emergency tracheotomy was performed as well.

Postoperatively, the patient was given anticonvulsant medication, and the chemotherapeutic measures were maintained for ten days. Gradually but definitely her condition improved. By the tenth postoperative day, she began to respond to questions and commands, but then aphasia was noticeable. By this time, numerous cultures of the spinal fluid and of the empyemic fluid and membranes, as well as of the pus found at operation, indicated no growth of organisms. The tracheostoma was closed on the fifteenth postoperative day. The patient continued to show steady improve-

ment in moving the right half of the body, in taking nourishment and in carrying out the acts of elimination. She was finally dismissed from the clinic, April 3, 1956, and was cared for in a hospital near her home from April 3 to 20.

During this period of hospitalization the ptosis of the left upper lid began to lessen and she was beginning to perceive objects and record incidents about the hospital. On April 13 she had a grand mal seizure of a few minutes' duration. Administration of sodium dilantin was begun immediately. Since April 20 she has lived at home, and apparently has suffered only one minor convulsive episode.

The patient was readmitted to the clinic and hospital in Rochester for re-examination, July 21, 1956. She was found to be alert. Her primary neurologic deficit was a mixed type of aphasia. She did not seem to appreciate the right side of the body as well as the left, and there was mild hyperreflexia on the right, but the grasp and strength in the right upper extremity were better than when she had been dismissed from our care. No ptosis of the eyelid remained, the optic fundi appeared normal with no evidence of a homonymous field defect, and there was no papilledema.

According to her sister, the patient takes care of her various needs by herself. She turns on the radio and finds her desired station, she cooks her own meals, makes her bed, dresses herself and combs her hair. She does have considerable difficulty in expressing herself, but apparently she understands what she reads in newspapers and in magazine articles. Until May of this year she seemed to be improving considerably in understanding of speech and comprehension of reading and in speaking, but since that time little improvement has been noted. Because of the convulsive episodes the patient is being given diphenylhydantoin sodium (1 capsule three times a day) in the hope that this measure will prevent any such seizures in the future. If the patient makes sufficient progress and no complication develops, a cranioplastic procedure will be justified and indicated, especially if the convulsive episodes persist.

It has been noted that when the bone flap has had to be removed because of an infective process and cerebral edema, the spells are better controlled after cranioplasty. The decision will depend, of course, on the patient's progress and her desire to have the operation carried out for cosmetic reasons or to control the convulsions if they cannot be controlled by medication.

Summary and Comment

The case of a middle-aged patient in whom developed the signs and symptoms of increased intracranial pressure, secondary to otitis media, has been described. Instead of an intracerebral abscess, a huge subdural empyema was found covering the entire left cerebral hemisphere. This was totally removed at once. Because of excellent preoperative chemotherapeutic management of this patient, no positive cultures could be obtained at the time of operation or postoperatively. The clinical improvement was dramatic, and justified the radical surgical procedure which had been applied.

Acute subdural empyema is a surgical emergency. It is thought to be based on thrombophlebitis of the cortical veins which, if of sufficient magnitude, precludes a satisfactory postoperative recovery. Its presence must be suspected in any patient with a history of sinusitis or draining ear who suddenly becomes gravely ill, is semi-stuporous, and has Jacksonian convulsions. (Frequently the convulsive episodes affect the lower extremity contralateral to the lesion, or both lower extremities if there is an interhemispheric collection of pus.) After a careful assessment of the available clinical and laboratory findings in such an acutely ill patient, the differential diagnostic possibilities must be analyzed. In addition to subdural empyema these include bacterial leptomeningitis, extradural abscess, brain abscess, and thrombosis of the superior sagittal sinus.

The early recognition of subdural empyema as

a severe infectious process is essential so that the organism can be identified and its drug sensitivity tested at the earliest possible moment in order that the correct antibiotics may be administered. When the infectious process becomes localized either in the form of an abscess or empyema of the subdural space, definitive surgical measures can be carried out in the hope of salvaging a patient who appears critically, or even hopelessly, ill.

It goes without saying that the primary source of the infection must be sought out and treated surgically and with extensive use of antibiotics to prevent recurrent infection.

The Management of Infectious Hepatitis

DONALD S. MATTSON, M.D.
Minneapolis, Minnesota

A HOST of viral-induced illnesses still await the emergence of some antibiotic which will suppress them as penicillin does the pneumococcus and as streptomycin does the tubercle bacillus. In the absence of a specific effective drug, the management of hepatitis has necessarily been based on the supportive measures, i.e., rest and a nutritious diet. The parade of hopeful, frequently disappointing trials of therapeutic measures has included every type of intravenous infusion, numerous antibiotics, variously administered multi-vitamin preparations, salt-poor albumen, high doses of vitamin C, the sulfur-containing amino acids, and many kinds of diet. The typical story of initial success followed by failure to reproduce those results has attended almost every trial. It seems reasonable, then, to consider the evidence supporting what have been the foundation stones of the management of infectious hepatitis, rest and diet. Even these have been seriously questioned during the past few years. There is also some need to consider the current status of the adrenal steroid hormones in this disease.

Diet

During the past decade there has been some challenge of the validity of each element of what was formerly considered without question to be the proper diet in the management of hepatitis, i.e., the high calorie, high carbohydrate, high protein, low fat diet. The high incidence of the disease during the second World War was not only a stimulus to the intensive study of the disease, but it also afforded an excellent opportunity for such study. Thousands of servicemen with infectious hepatitis were often grouped together and studies in these groups led to some very interesting conclusions. Darmady¹ studied the effect in British servicemen of a high protein diet (CHO-370 gm.,

Prot. 155 gm., Fat 100 gm.) supplemented by vitamin B complex, as compared with the usual diet of the British army (CHO 320 gm., Prot. 80 gm., Fat 60 gm.). In a series of sixty-one patients, thirty-two of whom were on the special diet and twenty-nine on the standard, he found no advantage for either diet. Gertzen² divided 311 patients into three groups, keeping the basic diet identical for each group (CHO 320 gm., Prot. 80 gm., Fat 80 gm.) but adding 65 gm. of fat, 135 gm. of protein, and 100 gm. of carbohydrate, respectively, to each of the three groups. He, too, could detect no definite difference between any of the groups.

Barker, on the other hand, has been a proponent of the high calorie, high protein diet and strict bed rest. Along with his co-workers, he investigated seventy-six cases to test the variable of the high protein content of the diet.³ (Table I.)

TABLE I.

	Number Cases	Per cent Discharged, Improved*			
NUMBER OF DAYS HOSPITALIZED		42	56	70	84
High protein	30	13	40	50	53
Average protein	46	4	9	15	22

*Days after admission.

Their patients eating a high protein diet recovered and left the hospital significantly faster than those on an average protein diet.

Leone et al,⁴ working with sixty-seven volunteer prisoners whom they inoculated with infected pooled plasma or plasma from known carriers, found that the total serum bilirubin (TSB) in patients eating a high protein (200 gm.) high calorie (4000 cal.) diet stayed abnormal longer than the group taking *ad lib* diet (94 gm. Prot. 2600 calories). His treatment groups were small, however, limiting the significance of these results.

In the light of these divergent results, Chalmers, et al,⁵ undertook a study which was extremely well controlled and well analyzed. Two hundred

Dr. Mattson is a Medical Fellow, University of Minnesota Graduate School; Medical Resident, Minneapolis Veterans Administration Hospital.

and thirty-two patients, divided equally, were fed either a high protein, high calorie diet (215 gm. Prot., 4060 cal.) or an *ad lib* diet (130 gm. Prot., 3510 calories). The high-protein diet patients were tube fed if necessary to reach the level desired, and the necessity of the diet level was continually stressed to the patients. The other group ate as they pleased and the importance of the diet was never mentioned. The duration of illness in the first group was twenty-two days, the second twenty-eight days. This reduction (six days or 22 per cent) was statistically significant to 0.01 per cent. In a second study of 200 patients by the same investigators, the relative effects of the protein content and the total calories were investigated. Results are indicated in Table II.

TABLE II.

Number of calories.....	4000	3000		
Per cent protein in diet.....			19%	11%
Per cent reduction in duration of illness	6%		14%	
Statistical significance.....	Not signif. at 5% level		Signif. at 5% level	

Serum bilirubin also was found to fall significantly more rapidly in the forced diet group. It would appear then that the high protein diet is useful in the management of infectious hepatitis. Only in fulminating disease or severe hepatic insufficiency is the high protein diet not indicated.

The belief that low fat content in the diet benefits patients with hepatitis was influenced by many factors. As Hoagland stated, fat was first restricted because of the mistaken concept proposed by Virchow that the biliary radicals were obstructed by bile thrombi,⁶ thus excluding from the bowel bile necessary for the absorption of fat. This was later encouraged by the finding that degenerative hepatic changes were accelerated by fat in the diet of experimental animals.⁶ It has been observed, however, that for this to occur the protein content of the diet must be very low. This does not occur in man and a low fat diet has several disadvantages, among them unpalatability (which is distinctly disadvantageous in a patient already anorexic) and difficulty in attaining high caloric levels. Hoagland et al⁶ found that patients eating 150 gm. of fat daily did just as well as, and possibly better than, similar patients eating only 50 gm. of fat per day. They gained weight faster than the patients eating 50 gm. of fat per day. Wilson and his co-workers⁷ found in 103

cases that a diet high in fat inhibited in no way their progress toward recovery.

Lastly, with regard to the diet, it has been suggested^{8,9} that lipotropic agents, notably choline, cysteine, and methionine, have a distinctly beneficial effect in the jaundiced patient. In two well-controlled series,^{5,10} however, these agents were found to create no observable differences.

Fig. 1.

Rest

A need for complete rest was long considered essential in the management of hepatitis. Barker, who first described what he called a “new clinical entity—chronic hepatitis,” was the leading advocate of a strict bed rest regime. In a study with Capps,¹¹ he demonstrated that the patients on strict bed rest were discharged from the hospital earlier than those allowed activity about the ward. (Fig. 1.)

The patients on strict bed rest, however, were also fed a high protein-high calorie diet in contrast to the routine army hospital diet fed to the others. The possibility that this was the significant variable was not considered. Capps and Barker¹¹ stated that “failure to go to bed during the acute icteric stage has apparently caused cases of only moderate severity to progress to a fatal outcome over a period of weeks.”

Kunkel et al¹² stressed the need of following every patient with frequent bromsulphthalein (BSP) tests and advised reinstitution of bed rest if any elevation occurred. They described thirty-eight patients who “suffered relapses” during a “leave” when full activity was resumed for the first time. They defined “relapses,” however, as any elevation of the BSP above 5 per cent, whether attended by any symptoms or signs or not. This definition probably requires some modification. Kunkel and Labby¹³ reported five patients with cirrhosis following hepatitis, two of which were said to be related to increased activity (wartime duties) during the acute illness.

The concept of rest in hepatitis seems reasonable and had been accepted without question until 1949 when Gardner et al¹⁴ examined sixty-eight servicemen who had had hepatitis six months to one year previously. He could find no relation between the degree of interim activity and the residual physical signs, symptoms or laboratory abnormalities of infectious hepatitis. Nelson and his co-workers¹⁵ examined seventy-nine patients who had done full-time duty between discharge from the hospital and follow-up. Mild symptoms of fatigue, anorexia, or upper abdominal pain were frequent (twenty-two of seventy-nine) but only six had any abnormal test of liver function and these abnormalities were slight. Only four patients had a combination of abnormal symptoms, signs and laboratory findings. All of these were mild. On discharge from the hospital, there had been a total of sixty-seven abnormal tests of liver function. On follow-up there were only twenty-eight. Abnormalities of both total and direct serum bilirubin (SB) decreased in incidence following discharge. However, BSP retention increased in incidence. From these data the authors concluded "that activity far in excess of that usually prescribed in acute hepatitis did not inhibit sustained recovery."

Swift et al¹⁶ divided ninety-eight patients into three groups during convalescence, one having graduated exercises requiring progressively greater effort, one on bed rest without exercise, and one group on fatiguing exercises from the outset. Convalescence proceeded at the same rate in all groups. Only when the direct serum bilirubin exceeded 3.0 mgm. per cent did exercise prolong the time for recovery.

Some¹⁴ have suggested that the reason for the more frequent relapses after resumption of activity in Barker and Capps' cases, compared to the studies mentioned above, was that the former were more fatigued from combat conditions and more poorly nourished prior to the onset of their disease. McFarlan,¹⁷ studying troop activities in New Zealand, North Africa, Sicily and Italy in relation to epidemics of infectious hepatitis in these areas, concluded that neither physical strain nor dietary deficiency were precipitating factors. Retrospective analysis of the data of Chalmers et al⁵ also revealed no such relationship. The latter study provided remarkable evidence that rest may not be an essential component in the treatment of this disease. Two hundred thirty-two patients were divided equally and placed on either a strict bed

rest or "ad lib" rest program. Those on strict rest were allowed one latrine visit per day, two showers per week, all other activity including meals being restricted to bed. Co-operation was carefully recorded, statistically evaluated and was found to be excellent. The ad lib rest patients were free to move about the ward at will. By the seventh day more than half of them were out of bed more than half the day. The two groups were vastly different in their level of activity. If duration of illness was defined as the first normal BSP (less than 5 per cent) combined with two consecutive normal total serum bilirubin (less than 1.5 mgm. per cent) determinations, then the average response to rest was a 10 per cent or three day reduction (twenty-seven to twenty-four days) in duration of illness in favor of the *ad lib* rest program. This, though, statistically significant to 5 per cent, was not significant if duration of illness was defined in some other way. Nowhere in this study, however, were the patients forced into activity. When they felt sick they were allowed to lie in bed, so that this study offers no evidence that rest is *not* advantageous when the patient feels sick. "It is still probable that enforced activity during the acute phase of hepatitis, as in any infectious disease, will make the patient feel worse, and may possibly prolong the disease."⁵ The *ad lib* rest program also has two distinct advantages. It removes a considerable fraction of the burden of patient care and it obviates that period of recuperation after any period of prolonged bed rest. One-half of the patients in this latter study were also started on strenuous physical reconditioning as soon as their laboratory values had returned to normal. This included various calisthenics and exercises, marches, long and short drill work, and organized athletics. It is of interest that a significant number of minor abnormalities developed in this group and also that these same abnormalities disappeared while they still participated in the exercise program. They were thus considered to be of little clinical importance. In only 4 per cent of the patients did either abnormal BSP retention or SB elevation develop. These, too, returned to normal while still on exercise.

Adrenal Steroid Hormones

The use of these substances was met at first with considerable enthusiasm, but it soon became apparent that one had to choose between what seemed to be a fair therapeutic response and the

complications associated with steroid therapy. One of the first reports was that of Sborov¹⁸ who treated fourteen patients with a single dose of ACTH daily, administered either subcutaneously or intravenously for ten days starting in the first week of illness. In the treated cases the mean SB dropped to normal in twenty-seven days; in eighteen control patients, it remained abnormal for fifty days. He stated that "in no instance did the ACTH adversely affect the course of hepatitis." Colbert et al¹⁹ were not so fortunate. In five patients treated with ACTH they obtained a "most striking result." The appetite and energy returned promptly and the SB showed a prompt fall in all cases, but the relapse in two of the five was worse than the original illness. "Untoward effects, including ascites, sacral edema, moon face, acne and hypertension, were noted in all five patients, and joint pains developed in four of the five patients upon withdrawal of the ACTH."

Evans et al²⁰ treated twenty patients with ACTH. No effect was noted in either BSP or SB lowering except for a prompt initial fall in SB. A "dramatic effect of improved sense of well being and an increased and often insatiable appetite" was observed. Four relapses occurred in these twenty patients compared to an incidence of relapse of less than 1 per cent in previously treated cases. Using cortisone²⁵ they noted a significantly more rapid fall of SB and BSP, but again relapses were noted in two out of ten cases. It was postulated that starting these drugs too early in the course of the disease or discontinuing them prematurely²⁶ may have been responsible for the relapses,²⁰ but further experience has not borne this out.

In the largest study reported to date, Sborov and co-workers²¹ treated forty-nine patients with varying doses and modes of administration of ACTH. He concluded that the duration of abnormal liver function tests grew shorter as more sustained adrenal stimulus was attained and that a definite therapeutic effect in cholangiolitic hepatitis was noted, but that no statistical difference between treated patients and controls was shown. Needle biopsy in all patients likewise showed no clearcut differences. The results obtained by Johnson and Bennett²² in twenty-two patients were similar to those of Sborov. He noted, in addition, complications of perforated ulcer, marked euphoria, rounding of the face and aggravation of a case of diabetes. The complications assume smaller pro-

portions, however, in cases of severe infectious hepatitis. Rifkin et al²³ reported four patients with homologous serum jaundice "going rapidly downhill" on routine therapy. A "remarkable clinical change following administration of corticotropin" was noted in each case. Evans et al²⁴ treated five patients with "severe (SB over 15 mg. per cent) hepatitis and observed a "consistent and rapid decrease in bilirubinemia and the relief of symptoms." Three of the five relapsed, however, to lesser degrees of chemical and symptomatic abnormality. Six cases described as "fulminant" all died in spite of treatment with ACTH. One must then choose in the routine case between the possibility of complications and the potential of benefit to the patient. The validity of using these drugs to increase appetite with consequent nutritional benefit needs further investigation. Their use in severe progressive or persistent disease is probably also indicated, but the utilization of these products in the routine case is questionable. There have been few well-controlled reports on their use. Further study is needed, but it appears that in the usual instance of uncomplicated infectious hepatitis the complications of steroid therapy and the associated incidence of relapse outweigh its possible benefits.

Relation of Treatment to Residual and Development of Cirrhosis

There remains one question which will certainly be answered with great difficulty. Does the type of treatment alter in any way the development of persistent hepatic insufficiency or predispose to the future occurrence of cirrhosis? The development or persistence of residual abnormalities following viral hepatitis has been studied repeatedly. Klatskin and Rappaport²⁷ examined 217 post-hepatitis patients, and found that 108 (50 per cent) had either symptoms referable to the liver, hepatomegaly or evidence of impaired liver function. The duration and severity of the jaundice appeared to be the only factors which bore any relation to the incidence of residuals. There was "no significant difference between those who had been kept in bed for the entire duration of the jaundice or longer, and those who had had bed rest for less than the duration of the jaundice." Post et al²⁸ found that forty-four of 117 patients had developed residuals. In five these were attributed to too short hospitalization. Kunkel and Labby¹³ described two patients who relapsed on

return to wartime activities who now have persistent elevation of BSP retention and hepatic tenderness. Chalmers et al⁵ felt that "chronic hepatitis" had developed in four patients but no effect of previous treatment could be ascertained. He stated that the "incidence of chronic disability and significant residual abnormalities observed in follow-up was no greater for patients permitted ad lib ambulation and started on strenuous exercise early than for those on the conventional treatment regimen." Nor is hepatic disturbance in the post-hepatitis patient evidence of causal relationship.²⁹

To answer the question, one must first determine what is significantly abnormal. In patients with abnormal symptoms or signs relative to the liver but with an histologically normal liver, which is of greater significance? It has been demonstrated that biopsy specimens are correlated poorly with clinical data. One must be aware of a number of factors other than the variables in treatment. For instance, one must differentiate infectious hepatitis and serum hepatitis, and also take into account the wide natural variation of the disease, the other possible sources of hepatic injury, the differences in virus type and constitutional differences in the host. Zieve has also shown that the incidence of significant residual abnormalities is small and the collection of a numerically adequate sample would indeed be difficult.³⁰ The demonstration of a relationship between treatment factors and residual abnormalities would be extremely valuable.

Summary

1. A high protein diet is of significant value in the management of infectious hepatitis, except where a severe degree of hepatic insufficiency is present.

2. A low fat diet is neither necessary nor desirable.

3. The lipotropic substances have made no significant difference in the course of the disease.

4. Strict bed rest is probably not necessary although strenuous activity during the acute stage of the illness is to be avoided.

5. The degree of activity during convalescence has no effect on the incidence of residual abnormalities.

6. ACTH and cortisone are probably better reserved for severe cases and excluded from the

management of the routine case, but further work is needed on this point.

7. The incidence of residual abnormalities following infectious hepatitis is probably low.

Continuation Study

Neurosurgical Aspects of Brain Abscess

WILLIAM T. PEYTON, M.D.
Minneapolis, Minnesota

BRAIN abscesses most often develop from middle ear and paranasal sinus infections, or they are metastases from pulmonary infections. They may also result from implantation in penetration head injuries.

Mode of Spread of Infection

Infection from otitic and paranasal sinus lesions spreads to form a brain abscess either by direct extension or by retrograde flow or thrombosis in veins. The veins are without valves in this region. Middle ear infections perforate through the tegmen tympani into the temporal lobe. The less frequent infections of the inner ear perforate through the posterior surface of the petrous pyramid to form cerebellar abscesses below the tentorium.

Frontal sinus infections may spread through the posterior wall of the frontal sinus and across the subarachnoid space into the frontal lobe or they may produce a spreading osteomyelitis of the frontal bone and this infection extends across the subarachnoid space into the frontal lobe, or it may pass across the subarachnoid space by retrograde flow or thrombosis in veins to the frontal lobe.

In penetrating head injuries, embedded pieces of bone or hair or other foreign material are very prone to produce an abscess. Hence, such wounds should be immediately debrided. Small metallic bodies are not equally infectious and, if deeply embedded so that removal may result in extensive brain destruction, they are best left undisturbed. Even in these instances an abscess may later form around the foreign body, sometimes many years after injury. Brain abscess is a common complication of congenital heart disease.

Pathologic Changes

Brain abscess as a rule develops subcortically in the white matter where the blood supply is less abundant. It begins as an area of encephalitis

with a necrotizing center surrounded by a poorly defined inflammatory zone. Eventually a capsule is formed. Abscesses continue to enlarge by thrombosis of blood vessels and necrosis of tissue. This enlargement occurs most frequently adjacent to the ventricles, so that the abscess is prone eventually to rupture into a ventricle rather than into the subarachnoid space.

Metastatic abscesses are usually multiple, and those from pulmonary infections contain anaerobic organisms and often are not capsulated. They were almost uniformly fatal before the advent of chemotherapy.

The subdural space, between the dura and arachnoid, is a very narrow space more potential than real. By retrograde thrombosis or perivascular spread of infection, this space may become infected and the limitation of such an infection then is similar to the localization of a pleurisy or empyema of the thorax, that is by adhesive inflammation to seal the arachnoid to the dura. The most fulminating subdural abscesses result from frontal sinus infections. They tend to spread posteriorly, either along the falx or over the cerebral convexity and may even extend through the tentorial notch into the posterior fossa. More will be said about subdural abscesses below.

Diagnosis

Brain abscess is often a treacherous lesion difficult to diagnose. Awareness of the possibility of a brain abscess is most important in its diagnosis. Rarely is it evident that the patient has a brain abscess when first seen by the neurologist or neurosurgeon. Often meningeal signs are the predominant feature and it is difficult to decide whether the patient merely has meningitis or an abscess with associated meningitis. Localizing signs, if present, suggest an associated abscess.

On the other hand, brain abscess may be so latent in onset that the primary infection is no longer a prominent feature. A very chronic brain abscess may be associated with minimal or no

Presented at the Center for Continuation Study, University of Minnesota, January 31, 1956.

signs of infection and present only the signs of an expanding lesion. This is especially true when a capsule has developed. As a capsule develops, all signs and symptoms may subside, especially the signs of infection, such as temperature, leukocytosis and meningeal irritation; the patient becomes more alert and headache disappears.

The symptoms of an abscess are due to a space-displacing lesion, tissue destruction and an infectious process with reaction to the infection. It has been said that the only symptom never absent in brain abscess is headache. Papilledema is present in approximately two-thirds of the cerebral and in one-third of the cerebellar abscesses. Brain abscesses may or may not have localizing signs. Seizures occur in about the same frequency that they occur in brain tumor, i.e. in about one-fourth of all cases. When a brain abscess is suspected, its presence and location are verified by ventriculogram or angiogram.

Since about 1925, when the treatment of brain abscess shifted to the care of the neurosurgeon, many factors have contributed to improved results, especially improved diagnostic procedures such as air injection (usually ventriculography), angiography, a better understanding of increased intracranial pressure and its management, and more recently chemotherapy and antibiotic therapy.

Some of the methods of treating brain abscesses that have been employed by neurosurgeons are:

1. Unroofing the abscess by removing the overlying bone, dura and cortex to allow the abscess to herniate to the surface (King, 1924).
2. Aspiration of the abscess without drainage (Dandy, 1926).
3. The insertion of a tube into the abscess for continued drainage, and recently this has been combined with periodic instillation of antibiotics through the tube.
4. Total extirpation of the abscess (Vincent, 1936).

Present day surgical treatment of brain abscesses is varied to suit each case, one or other or a combination of the above procedures being used. There are three objectives to be attained in the treatment of a brain abscess, i.e., to save life, preserve or restore function, and avoid sequellae, especially epilepsy.

Abscesses from paranasal sinuses may be treated

by aspiration only, tube drainage or excision. The recent trend is to aspirate the abscesses until they become encapsulated and then excise them. When aspirated, thorotrast may be injected. It is phagocytosed by the wall of the abscess and then by x-ray the size and location of the abscess may be followed. Excision of an abscess in the fulminating stage before capsule formation is done only under duress, when the abscess cannot be otherwise controlled, and excision is necessary to save life regardless of the extent of loss of function.

Abscess from penetrating wounds, such as war wounds, requires, as a rule, early operation with excision of the abscess and debridement of the area as soon as the abscess is recognized.

Metastatic abscesses, even when single, as they are in 40 per cent of cases, tend to be more malignant, rapidly progressive and nonencapsulated because of the debilitated condition and low resistance of the patient, and because they are most often caused by an anaerobic organism from a pulmonary lesion. Multiple metastatic brain abscesses are still rarely cured.

Mortality

In a recent report¹ the mortality rate is given on 295 patients. The mortality for those treated before the use of penicillin was 53 per cent, in contrast to a 27 per cent mortality for those treated with penicillin. The greatest reduction in mortality was in patients with cerebellar abscesses, where it was reduced from 70 per cent to 9 per cent, and in patients with cerebral abscesses secondary to bronchogenic abscesses, where it was reduced from 100 per cent to 32 per cent. In other cerebral abscesses, mortality was reduced only from 36 per cent to 30 per cent.

Sequellae

Of 175 patients followed¹ 8 per cent were disabled by profound, motor sensory or visual defects. Another 8 per cent had slight defects, and 84 per cent had no significant defect.

When the capsule is not excised, there is often recurrence at the same site (seven recurrences in 88 cases¹). With excision of the capsule, there is seldom late recurrence. Epilepsy, present in 27 per cent of patients with cerebral abscesses before operation, was present in 47 per cent of the survivors.¹ That is about the same incidence of epilepsy that occurs after penetrating missile

wounds of the brain. Removal or nonremoval of the capsule does not seem to affect the incidence of epilepsy after brain abscess. The first seizure appears within one year after treatment of brain abscess in about two thirds of those developing epilepsy, but it has first appeared as late as fourteen years. Every patient recovering from brain abscess should be put on anticonvulsive drugs and kept on them indefinitely; if not, status epilepticus may suddenly develop and the patient may die in the attack.

Subdural Abscess

Subdural abscesses, as stated above, occur between the dura and arachnoid. They are quite rare. They arise from otic infections or from virulent frontal sinus infections. Those from frontal sinusitis are prone to be very acute and fulminating, spreading rapidly over the medial side of the hemisphere along the falx or more lateral over the convexity of the hemisphere. Before the use of antibiotics, they were almost uniformly fatal in this early spreading stage even before the diagnosis was made.

These patients are bedridden and the infection

spreads by gravity in a posterior direction. If it spreads along the midline, it produces focal Jacksonian seizures in the leg, with paralysis and sensory disturbances in the leg and, as it extends still further posteriorly along the midline, it produces a homonymous visual field defect. If it spreads more lateral over the convexity of the hemisphere instead of along the falx it produces focal seizures in the arm and face, aphasia and paralysis or conjugate deviation of the eyes toward the side of the lesion.

Before the employment of antibiotic therapy these subdural infections were almost uniformly fatal, but now they tend to become chronic with localized collections of pus and survival is possible with early and adequate drainage. They are best treated by multiple trephine drainage openings made at the site indicated by the clinical findings or it may be necessary to use ventriculography to locate collections of pus.

BRONCHOGENIC CARCINOMA

Case Study, Minneapolis Veterans Hospital

Presenting complaint: Fever, cough and wheeze, developing during hospitalization for treatment of a gastric ulcer.

A white man, sixty-one years old, was admitted to the hospital with a twelve-year history of epigastric pains, and a diagnosis of peptic ulcer established previously. The ulcer was in the pylorus and failed to show x-ray improvement after two weeks of intensive treatment; surgery was advised. Chest x-ray was negative. There was a history of mild chronic cough and occasional wheezing, with dyspnea on slight exertion thought to be due to chronic bronchitis and emphysema. Operation for ulcer was scheduled on the thirty-second hospital day.

On the day prior to scheduled surgery a fever of 102° was noted, with wheezing and signs of consolidation in the left lower lobe. There was no antecedent respiratory infection. The operation was canceled, and a diagnosis of pneumonia was considered on the basis of chest x-ray findings. The possibility of bronchogenic tumor was considered but bronchoscopy was delayed for three weeks during a trial of antibiotic therapy. The lung lesion did not disappear.

Bronchoscopy revealed a tumor nearly occluding the left main bronchus, 2.5 cm. from the carina. Biopsy showed squamous cell carcinoma. Inspiration-expiration films indicated that there was exchange of air on the left, though auscultation suggested exchange was limited.

The patient had a vital capacity of 1.8 liters exhaled slowly, and was dyspneic on slight exertion, such as walking down the hall. For these reasons several of the staff felt that operation could not be tolerated. Others thought that the left lung was largely functionless, and that there was a reasonable chance that surgery would be successful.

The latter view prevailed, and a radical pneumonectomy was performed thirty-eight days after the initial febrile episode. The tumor was localized in the left main bronchus, which was now completely obstructed, and twelve nodes sectioned were negative. The patient recovered uneventfully and was less dyspneic on walking the halls after surgery than he was before. With nodes being negative, he has a reasonable chance for cure. Operation for the pyloric ulcer will be carried out later if needed.

Comment: This case illustrates the difficulty of making an early diagnosis of bronchogenic carcinoma. The findings developed while the patient was in the hospital, yet operation was delayed five weeks more than it would have been if a complete study had been done immediately.

This patient also furnishes a lesson in judging operability of pulmonary lesions. If the lung to be resected is largely nonfunctioning, operation may be successfully carried out in spite of a small respiratory reserve.

"SECOND LOOK" SUCCESS

Case Study, Minneapolis Veterans Hospital

Presenting complaint: Crampy abdominal pain, beginning three years before first admission.

The patient, a white man, thirty-six years old, was first admitted to his local hospital in January, 1952. His abdominal pains had become progressively worse and had been most pronounced after ingestion of food. He also had anorexia, occasional vomiting, and had lost thirty pounds during the preceding year. He was operated upon in his own community and found to have an adenocarcinoma of the terminal ileum, with attachment to the right side of the bladder. The tumor and twelve inches of ileum were resected. Pathologic sections were reviewed at the Veterans Hospital and the diagnosis was confirmed.

The patient was referred to the Minneapolis Veterans Hospital in February, 1952, for possible roentgen therapy to the operative area. Examination showed an emaciated patient with a well-healed abdominal wound. X-ray studies disclosed two stones in the right renal pelvis. Cystoscopy was negative. Barium enema showed irregularity in the terminal ileum. It was decided to re-explore the abdomen; two months having elapsed since the initial operation.

A nodule of adenocarcinoma 2x2 cm. was found attached to the serosa of the bladder, and several large nodes were present in the mesentery of the terminal ileum near the previous anastomosis. The nodule was removed from the bladder by cutting down to, but not through, the mucosa. Resection of 62 cm. of ileum and 19 cm. of ascending colon, with attached mesentery, was carried out. No tumor was found in the bowel or nodes.

The patient recovered and went home, but returned seven months later because of severe right costovertebral angle pain. Retrograde pyelograms showed obstruction at the right ureteropelvic junction. At exploration of the abdomen, a 1.5 cm. nodule was found in the peritoneum on the right side of the bladder. It was pedunculated and easily excised. The right ureteropelvic junction was also explored, and a 2x3 mm. stone was removed. This finding, rather than the metastatic tumor, probably explained the patient's symptoms on this admission. The patient recovered uneventfully and went home, where he regained his normal weight. He had no symptoms, but was advised to have an exploratory operation for possible recurrent cancer. This was performed eight and one-half months after the preceding operation. Many small nodules were excised and sectioned. All except one were granulomas, but a 1 cm. lymph node in the sigmoid mesentery contained adenocarcinoma.

The patient went home and was symptom-free. He returned for his fourth surgical look five months later, which was entirely negative. He required another operation eleven days after this for lysis of adhesions which were causing small bowel obstruction. Since then he has done well. He was last seen thirty-two months after the last procedure, or four years and eight months after the first operation, and will continue to be followed.

Comment: This case illustrates an apparent success with the "second look" procedure for cancer. Four operations were done in the absence of symptoms which could be attributed to residual cancer, and small metastases were found at the first three. Cure of this patient is possible, though of course, not certain. In any event the patient is surely better off than he would have been if the metastases, which were found by virtue of their appreciable rate of growth, had not been removed.

PAROTID CARCINOMA?

Case Study, St. Barnabas Hospital

During March, 1956, a healthy woman, sixty-seven years old, was admitted to St. Barnabas Hospital with a history of a gradually appearing painless lump below the lobe of the right ear and posterior to the angle of the right jaw. This mass had made its first appearance approximately six months prior to the time of admission.

The patient was operated upon under general anesthesia for local excision biopsy of the tumor and the mass was found to be attached to, but not considered as a definite part of, the tail of the parotid gland. A wide removal of the local lesion was performed including normal appearing surrounding tissue. The frozen section diagnosis reported probable metastatic carcinoma probably of the squamous type. No further surgery was performed until a further searching examination of the nose, throat, and adjacent areas had been made.

The paraffin-stained sections revealed the tumor to be a muco-epidermoid carcinoma of an "intermediate grade of malignancy," but there was some difference of opinion among various pathologists as to the classification of this degree of malignancy. The patient was operated upon following the recommendations from the St. Barnabas Tumor Conference, and a total parotidectomy was performed with an in-continuity neck dissection on the involved side, and with preservation of the facial nerve. The consensus of the Tumor Conference was that, since this lesion was not a definitely high grade type of invasive cancer, and furthermore, since it was located in its parent origin at the very lower portion of the parotid gland, it would be reasonable to preserve the nerve.

The patient recovered without event from the

THE PSYCHO-EDUCATIONAL CLINIC

The Psycho-Educational Clinic is a department of the College of Education, University of Minnesota. It offers diagnostic and remedial services to children who have encountered special difficulties in school learning. Beginning in the Fall of 1956, the Clinic will expand its services to include diagnosis and counseling in the areas of special education (handicapped and gifted children) and educational and vocational guidance for teenagers. In conjunction with this service, the Clinic has training and research programs.

The staff of the Clinic consists of the five regular faculty members of the University who carry part-time assignments in the Clinic, four graduate student clinicians, and a secretary. Some graduate students also participate directly in the activities of the Clinic under supervision of the Clinic staff. The training of all staff and students is in the area of educational psychology and closely allied disciplines. There is *no representation* of the fields of medicine, psychiatry, social work or speech pathology on the staff.

The most common referral concerns reading difficulty. Referrals for reason of poor progress in other basic school subjects (arithmetic, spelling, handwriting, et cetera) are less common. Other common bases for requesting Clinic services include school readiness problems and special abilities and talents. The Clinic also offers limited services in the case of mentally and physically handicapped children. Age limits are from five (school readiness) through eighteen (high school).

The first step in making a referral to the Clinic is simply to call or write to the Clinic asking for referral forms. Usually the parents or school officials make this first contact. When the referral forms have been completed and returned to the Clinic, they are studied, and if it appears that the Clinic is an appropriate diagnostic agency, the parents are contacted by phone or letter to arrange specific appointment dates. Referral procedure is modified in the case of referrals by physicians, social workers, welfare agencies, and others. In every case, however, it is required that the parents and a professional person (usually school

officials) agree to and participate in the referral.

Typically, a diagnostic study will take about three half-day appointments. The Clinic attempts to collect information about the child, his family, community and school in order to offer insights as to the nature of the problem and suggestions for rehabilitation. A typical study would include: (1) a parent interview; (2) individual mental testing; (3) screening tests for possible vision and hearing difficulties; (4) personality evaluation (including tests, observation and interviews); (5) survey testing in basic school subjects; (6) detailed diagnostic testing and evaluation in the areas of the difficulty; (7) a final parent interview; (8) a full report of findings, interpretations and recommendations to the referring agency or person (usually school officials). No written reports on diagnoses are given to parents, but major results are summarized in the final interview. The fee for the educational diagnosis described above is \$30.00. In cases requiring less than three half-days, the charge is at the rate of \$3.50 per hour. A limited scholarship aid, provided through the Greater University Fund, is available to those unable to pay the full fee.

The Clinic offers remedial services only after a diagnosis has been completed and then only in cases where its facilities seem definitely suited to the needs of the child. Remedial tutoring in reading is the most frequent service rendered. All remedial services are on a highly individualized basis. During the school year, a limited number of children can be served. Each child comes to the Clinic for the period from 9:30 to 11:30 a.m. each school day. During the Summer, a ten-week Remedial Reading School is in operation. This program begins in mid-June and ends in late August. Children attend five days a week from 9:00 to 11:00 a.m. Fees are charged for remedial tutoring at the rate of approximately \$3.00 per day.

The Clinic operates five days a week through the entire year, except for the month of September and during school holiday periods (Christmas, New Year's Day, et cetera).

MAYNARD C. REYNOLDS
University of Minnesota

ADVERTISEMENTS?

A Yale Ph.D. (English literature), stationed in the Aleutians, once told us that somehow the overseas editions of the *New Yorker* (for example) didn't hit the mark. His idea of luxury, he declared, was *not* to sit down and read such issues emasculated by removal of all the advertisements, but rather to sit comfortably and read the full-fledged magazine so he could day dream through the ads and savor the high standard of living to which they always beckoned him. We don't put MINNESOTA MEDICINE in the same class with the *New Yorker*, but we submit that the sage observation by our erudite friend is as true for this magazine as for any lay periodical.

An occasional ruffle on our quiet editorial waters signifies someone's conviction that the advertisements in MINNESOTA MEDICINE are just so many pages thrown away. With that someone, we disagree.

First of all, our advertisers seek to inform us, to inform you of their products and services, old and new. This desire to inform you is based on the earthy premise that if you don't know about their products, you can't possibly buy them and therefore they fail as a business enterprise. Hence, the advertiser does his best to bring you information that will be of value to you in your practice, and thus keep you interested in his products and services.

Secondly, our advertisers are reliable. They pay for the space their ads occupy in MINNESOTA MEDICINE. They are all canny folks and are not going to spend their advertising budgets trying to convince wary physicians of the value of a worthless product; they're going to advertise what they know has value to you. Economic factors alone prevent an unreliable fly-by-night firm from using MINNESOTA MEDICINE advertising space. In addition, the staff of MINNESOTA MEDICINE does its best to accept ads only from known, reliable advertisers.

Thirdly, for those of you who have an eye to our own budget, the advertisers bear the lion's share of the costs of publishing MINNESOTA MEDICINE. How else do you think you get this magazine at a net cost to you of 5 to 10 cents per issue?

Now finally, we urge you to get the full value out of each issue by giving the ads a leisurely going over. They're worth it on all counts.

H.G.M.

BLUE SHIELD AND THE ECONOMICS OF MEDICINE

Why should any doctor take a special interest in his Blue Shield Plan?

For one thing, the physician has a vital professional stake in the success of his own medical prepayment plan. This plan demonstrates the doctor's determination to solve the basic problems of medical economics on terms that will assure him a continuing opportunity to give his patients the best care he is capable of rendering.

Secondly, and perhaps most important, through Blue Shield the medical profession can continue to control the economy of medical practice.

Blue Shield pioneered the development of pre-paid medical care. And, while many other agencies are now providing cash benefits for medical services on an expanding scale, only Blue Shield—because of its intimate relationship to organized medicine—is consistently endeavoring to relate its benefits to the physician's normal charges. Only Blue Shield—because of its non-profit organization—has as its basic purpose the provision of maximum service to the patient, with an adequate compensation to the doctor. Any profit derived from Blue Shield operations goes to the patient in broader benefits, or to the physician in more adequate payment—not to a third party.

If other organizations unrelated to the medical profession were to take over the entire voluntary prepayment program, then control of the basic economy of American medicine would pass completely out of the hands of the medical profession.

Blue Shield has grown into a big business, in terms of the 37 million people enrolled and the more than \$350 millions now paid each year in medical benefits by the Plans. But Blue Shield is big only because the medical profession has fashioned a big instrument to do a big job—and the public has given Blue Shield a big reception!

PROFESSIONAL RELATIONS COMMITTEE

Blue Shield Medical Care Plans

Chicago, Illinois

ENGRAVING—POINTS TO REMEMBER

When ordering engravings, it is well to keep in mind that there are certain things to specify in order to insure obtaining the best results in printing.

— This is the fourth and final editorial in a series on the subject of photo engraving.

1. Be sure the engraver proofs your work on the paper that will be used in the final printed job.
2. If the work is in more than one color, be sure that color bars are proofed with the job in the direction of inking. This will determine the quantity of ink used on the proof.
3. The engraver should use inks supplied or specified by the printer. This will insure the same result that the printer will obtain when printing.
4. In a job of more than one color, the proof should be printed in the same rotation as the printer will follow.
5. The proof should be printed with no make-ready. This will show the true value of the plate.
6. Whenever possible, the work should be proofed on the same stock as the printer will use. With the same inks, rotation of colors, and identical stock, you are insuring yourself against disappointments.

There are many terms in common usage in the graphic arts' industry that are sometimes unfamiliar—perhaps a brief reference to them will be helpful.

Backing up—Metal backing soldered to plates—generally to make them 11 points thick for printing or making pattern plates.

Base—Wood or metal upon which plates are mounted.

Bearers—In photoengraving—the dead metal left on a plate to protect the printing surface during electrotyping.

Ben Day—A method of laying a tint or screen (dots or lines) to obtain tones or shadings of color off the solid color.

Bleed—An illustration that extends to one or more edges of a printed page.

Blowup—As term implies—an enlargement from original size.

Burr—Metal turned up above printing surface by routing machine.

Combination plate—Halftone and line work combined on one plate by stripping the negatives together as one—and then etching for depth for both line and halftone.

Drop out—A halftone having no halftone screen in the highlights.

Flush blocking—Trimming printing plate so that plate and block on which it is mounted are flush.

Fugitive colors—Colors which are not permanent but fade when exposed to light.

Key plate—The plate in a set of color plates that carries most of the detail.

Magnesium plate—A halftone or etching made on magnesium—which is lightweight but strong, adaptable for high speed etching—usually 11 points thick.

Negative—A photographic image of original. It can be on paper, film, glass or metal.

Routing—Cutting away of non-printing metal or surfaces.

Tint block—A solid plate used in printing a light flat color.

Transparencies—Transparent positive photographs in black and white or color.

Work and tumble—Printing the second side of sheet, by turning over from gripper to back—using the same side guide.

Work and turn—Printing the second side of sheet by turning it over from left to right—using the same edge of the paper as the gripper.

Photo Offset

Another printing method in very general use incorporates many of the same steps as used in letterpress. Because it plays such a big part in the graphic arts field, it is important that a somewhat brief outline be given to it. One advantage is the versatility of the method since one can print by the offset method on any kind of paper—that is the surface may be rough or smooth and yet a halftone of any screen can be used—fine or coarse. This is primarily due to the fact that instead of printing directly on the paper from a rigid metal plate, it is transferred or printed on a rubber blanket fixed on a roller or cylinder and then offset onto the sheet of paper. Because this printing is done from a rubber blanket which will conform to irregularities in the surface of the paper, there is no problem of screen to contend with. The method is particularly suited to long runs—because of the high speeds of the presses used.

It is hoped that the very brief descriptions given in this series of editorials on photoengraving have given a little clearer picture of methods and steps involved. Understandably, the steps have been over-simplified in order that such a big area could be covered briefly.

W. W. CHREIMAN

MINNESOTA HEART ASSOCIATION

Among a dozen volunteer health agencies in our state, none shows greater promise of becoming a major force in the struggle for better health among our citizens than the Minnesota Heart Association. The physician under constantly increasing responsibilities of medical patient care finds little time for consideration of the place and importance of the voluntary health organizations in his own community, county or state and may lose sight of the valuable contribution that an enlightened and informed public may make toward the advance of medical care.

Last year, the people of Minnesota gave to the American Heart Association almost one-half million dollars to advance the support of cardiovascular research, and professional and lay education in problems of cardiac disease. Thus, in a

short space of eight years since the inception of the Minnesota Heart Association, it has gained the confidence of the citizens of Minnesota. The Minnesota Heart Association was founded by physicians, a group of internists interested in the advance of our knowledge of heart disease. In 1948, the Minnesota Heart Association became an affiliate of the American Heart Association and the goal of this organization was, and continues to be, that of supporting and stimulating research in cardiovascular disease and to promote professional as well as lay education in cardiovascular disease. The Heart Fund, the money raised through public contribution, provides the financial support.

In 1951, the Minnesota Association of Life Underwriters sensed the importance of this growing organization in the field of better health and agreed to accept the leadership for the annual solicitation of funds. The dynamic leadership provided by this organization is reflected by the fact that last year a total of 38,000 volunteer workers aided in the Heart Fund drive and a total of \$460,243 was contributed. What is being done with this money that has been provided by a generous public?

We are certainly not unaware of the responsibility placed on us to see that these funds are expended where they will create the greatest health return value to the public. The physician, more readily than the layman, is willing to accept the fact that progress in the fight against cardiovascular disease lies primarily through research, and the Board of Directors of the Minnesota Heart Association, consisting of men and women in both medical and nonmedical fields of interest, has continued to maintain the primary goal of support of cardiovascular research with the funds entrusted to it.

A committee of the Minnesota Heart Association on Research Allocation has recently assigned financial support to fifty-five cardiovascular research projects in Minnesota. Total American Heart Association and Minnesota Heart Association allocations reached \$314,000. The University of Minnesota has been the largest recipient of these funds, owing to the unusual facilities and interest in cardiovascular disease and excellent personnel of research capacity at the University of Minnesota Medical School. The Mayo Clinic has not requested grants from the Minnesota Heart Association for support of its research program but fellowships in cardiovascular research

have been assigned through the Mayo Foundation. Other institutions receiving grants for cardiovascular research are the Mount Sinai Hospital, Minneapolis, and Ancker and Miller Hospitals in St. Paul. Unfortunately, a large number of requests from qualified investigators for research support must be either reduced in amount or rejected because of lack of available funds. Adequate support for all qualified requests for research-support in cardiovascular disease would require an increase from 50 to 75 per cent in the funds now available.

In education, the Minnesota Heart Association continues to present factual information to the public and utilizes every tool at its disposal for public information and communication. Through the growing interest of both professional and lay personnel in the heart program, Heart Councils now are active in twenty-seven counties in Minnesota. Television and radio programs and an excellent film library, as well as information through pamphlet form, are being presented to the public in an effort to obtain closer understanding between the physician and his patient with problems of heart disease.

Another vital responsibility of the Minnesota Heart Association is in the field of professional education. Advances in cardiac research, diagnosis and treatment of cardiac disease are being presented to the physician under the stimulus and support of the Minnesota Heart Association in the form of lectures by outstanding authorities in the field at County and State Medical Society meetings and through major symposia on heart disease. These latter symposia have brought international recognition to Minnesota, owing to the excellence of the programs arranged.

Modern Concepts of Cardiovascular Disease, a monthly publication presenting an authoritative review of current cardiovascular problems, is sent free to any physician in the state requesting it. The *Heart Bulletin* is at present being sent to 1,500 physicians in the state as a service in professional education and the current "Concepts" page in MINNESOTA MEDICINE is directed by the professional education committee of the Minnesota Heart Association.

Requests for financial support of patient medical care for those suffering from cardiac disease come to the Heart Association frequently. These requests, of course, cannot be granted but the

office of the Minnesota Heart Association offers referral help for these patients through proper medical and welfare agencies.

Of all funds raised through the Minnesota Heart Association, 75 per cent remains in Minnesota to carry out the work of the Heart Association; the remaining 25 per cent is sent to the American Heart Association with which Minnesota chapter is affiliated. Owing to the excellent research facilities existing in Minnesota, the American Heart Association has consistently returned more funds to the state than is sent to it by the Minnesota Heart Association.

Analysis of state and national research allocations in Minnesota reveals the fact that 64 cents of each dollar contributed to the Heart Fund is expended on cardiovascular research. Naturally, the Minnesota affiliate is very proud of the program established in this state in support of cardiovascular research and is equally proud of its ability to raise sums of money from a generous public for its goals at a cost of less than 9 cents per dollar. Staff members are indeed confident that the physicians in Minnesota will continue to lend their moral as well as their financial support to the Minnesota Heart Association.

ROBERT L. PARKER, M.D.

LOANS AND SCHOLARSHIPS FOR MEDICAL STUDENTS

One of the major items of interest of the present Medical Student Committee is financial aid for medical students. Finances are a pressing problem to most medical students, and the Committee feels that this problem is not being met as adequately as it might be met. Accordingly, we are seeking to establish a more effective program than is presently offered at the University.

We feel that there is a need for three main types of financial assistance. The scholarship program at the University is improving all the time. The major contributor to this program has been the Minnesota Medical Foundation. These scholarships are awarded on the basis of need as well as scholarship. They are well publicized and much sought for. Complaints from other students that these scholarships have been inequitably distributed have dwindled markedly. Indeed, the Foundation is learning the art of giving money away. It is true, however, that it is extremely difficult for a Freshman to get a scholarship un-

less he has a four-year degree from one of the State Colleges. Nevertheless, the Medical Student Committee heartily endorses the scholarship program and hopes for its expansion.

The Committee feels that two other types of financial assistance should be offered, which at the present time are woefully inadequate. We believe that a grant-in-aid program should be established whereby the student in acute financial distress upon some rare occasion might receive a financial gift without the fanfare associated with a scholarship. Finally, we think that the present loan system is antiquated and insufficient. We feel that a student in medical school should be a good loan risk unless he is in dire scholastic distress.

To obtain a University loan at the present time is a very tedious, humiliating, and often unrewarding procedure. The maximum amount that a student can borrow from the University is \$500 in any one year or a \$750 total, regardless of how many years are spent at the University.

Just how many medical students really need a loan from the University is not actually known. It is safe to assume that the few medical students who really do need to borrow will need to borrow more than \$750 in four years.

To evaluate these needs more accurately, the student body is being surveyed. Student Committee members composed and distributed questionnaires recently to every student. Students were asked to evaluate their needs and their sources of support, among other things. The Dean's office sponsored the survey, but its results have not yet been computed.

The Medical Student Committee is certain of the need for financial assistance for medical students, and hopes to be able to make some more specific recommendations based upon the survey results.

THE MINNESOTA EUGENICS SOCIETY

The Minnesota Eugenics Society existed between 1922 and 1930. It was at its peak from 1925 to 1927, and it was in 1927 that Dr. Dight corresponded with President Lotus D. Coffman of the University of Minnesota concerning the possible Institute of Eugenics which Dight envisaged at the University. Dr. Dight wrote his will that year and bequeathed his estate to the University for that purpose. It is rather startling

that none of his other multitudinous interests, such as better training for nurses and other public health projects, were provided with even token bequests!

The provisions for the eventual utilization of his estate by the University were clearly written and at the same time general enough in nature so that they would be adaptable to a changing environment. In return for the bequest, the University was to provide academic instruction in human genetics, carry on research in the field, provide a free counseling center for the public where the people could obtain answers to their questions about heredity, and finally to establish new eugenics societies. It was no doubt apparent to the University that Dr. Dight's estate was inadequate for the support of such an ambitious program. However, there was sufficient enthusiasm for Dr. Dight's unique concepts so that when the bequest eventually materialized, it was accepted by the University.

Dr. Dight did not decrease his personal activity in the field of eugenics, even though the eventual disposition of his estate had been provided for, and his Eugenics Society was defunct. Between 1921 and 1935, more than 300 of his letters on eugenics were published in the Minneapolis daily newspapers. In 1927-1928, he gave a series of eleven talks over station WRMH and, in 1933, a series of twelve lectures over the same station. In 1935, the *St. Paul Dispatch* reported on an address which Dr. Dight gave before a group of 250 people. He was then seventy-nine years old.

Everyone must die, or social problems would develop which would seem insoluble even to Dr. Dight. His demise came on June 20, 1938, when he was eighty-two years of age.

A review of Dr. Dight's accomplishments shows a man intellectually in advance of his times. He was a radical—one who wants to try something new and is sure that it will work while most others doubt it. His idea of prepaid medical care is now acceptable to almost everyone. Few who have heard of typhoid fever or brucellosis would oppose his crusade for compulsory pasteurization of milk used by the public. There are still many who would oppose his crusade for voluntary sterilization of the unfit, and for the fit whose genetics indicate a serious likelihood of the production of further abnormal children. The opponents of voluntary sterilization are more strongly entrenched than were the milk companies that op-

posed pasteurization, but no group can hold back permanently the benefits medicine can bestow.

It would not be fair to judge Dr. Dight merely by the amount of legislation which he inspired, significant though it was. The endowment which one leaves at his death is the only thing of significance. The endowment may be a collection of bird prints, good heredity in your offspring, teachings worthy of reproduction, or the few dollars and the small library left by John Harvard. Cash without ideas is not enough—but it is very useful in almost any situation. Dr. Dight left some very large ideas and a little of the wherewithall needed to activate them. The University has faith that money will come from somewhere to ensure the proper execution of its compact with Dr. Dight. Dr. Dight's basic concept that man is susceptible to genetic improvement will not die.

TELEPHONE OF THE FUTURE

What will the telephone of the future be like?

No one knows exactly, even the telephone engineers themselves. But they have some ideas that may prove to be practical. If they work out, tomorrow's telephone will probably do many things undreamed of by today's telephone users.

Its appearance will undoubtedly undergo radical changes. Some models will be made smaller and more streamlined to a point where they can be carried around in one's pocket. The base of the instrument perhaps can be eliminated, the dial made much smaller, and the transmitter would become a small microphone located in the center of the dial. The whole instrument may not be much larger than an electric razor.

It may not even have a dial at all—push buttons will be used instead. In fact, on the more recent long distance switchboards, operators are now using push buttons instead of dial wheels to dial numbers in distant cities.

Telephone scientists are thinking up ways to make it easier for the user to place calls. Maybe a pre-set arrangement can be developed so that many of the numbers called frequently could be set up in advance. Then all one would do would be to select the number wanted, punch one button, and the apparatus would dial the number. This might be a number in the community or in some city across the country, because

each person would be dialing his own long distance calls as well as local calls. If the line was busy, he would replace the receiver, and when he lifted it again a few minutes later, the equipment would dial the number again automatically.

Speaking of the lines being busy, telephone engineers are thinking about a signalling device that would let one know that another call is waiting. By some sort of switch, the call of the person already on the line would be held while the waiting call is being acknowledged and then the first call would be resumed.

Going a little further into the realm of the imaginative, the day may come when any mechanical means of dialing will not be used at all, but the voice will be used instead. That is, the person telephoning will simply speak a number, and electronic equipment will translate the sound waves of his voice into electrical impulses.

This has been done in the laboratory, but in practical application, the difficulties are enormous: how to get the equipment so it will recognize the number whether it be delivered in a soft southern drawl, or with a midwest twang; whether it comes as the voice of a nice little old lady or a brash teenager. This one is a long way off, say the telephone engineers.

Some day we may wear telephones on our wrists! For short range conversation, telephone research people are thinking of a small radio-telephone about the size of a wrist watch, powered by tiny long-lasting batteries and using transistors instead of vacuum tubes.

In the future, the person who starts his conversation with "Guess who this is" may become a thing of the past because some models of tomorrow's telephone may include a TV screen so that the person on the other end of the line may be seen.

Many of these ideas are already being tried experimentally. Others are just in the "maybe-some-day-we-can-do-this" stage. Whether they ever materialize or not will depend on many things: technical progress, whether there is real public need, how much they will cost and other factors. But changes are coming. To say they aren't would be comparable to a report made by a patent office commissioner in the year 1848. He said all worthwhile inventions had already been made!

NORTHWESTERN BELL TELEPHONE COMPANY

REHABILITATION IN PULMONARY TUBERCULOSIS

The Principles of Rehabilitation and Vocational Training

The search for an immediate assessment of the working-potential of the patient still continues; it has not been found in formulae, from graded exercise to sedimentation rates. Some physicians hope that the time factor alone will give the answer, just as it has given the only safe answer to prognosis on breakdown; others, without any preliminary test, place their patients in categories immediately following the stage of active treatment, boldly stating that they are fit full-time, fit part-time, or unemployable. This is why many younger clinicians who pin their faith on the efficacy of modern therapy say that there are now only two types of patients, convalescents and failures, the former requiring only a toning-up process of a few weeks before return to full work, the latter condemned to the placebo of home work or occupational therapy which will replace permanent hospitalization.

Such physicians forget two lessons of the past which are individual to each patient; first, that the only test of working potential is to place the patient under observation in the actual conditions of industry; second, that all after-histories show variations, often quite unexpected, in the two years following discharge from hospital or sanatorium, and equal variations during the danger period of an additional three years.

The return to full work should be slow, even for the machine worker, and especially if he is learning a new trade. The mental concentration required can, in itself, be disastrous; a close watch is necessary on its physiological and functional effects. If at all possible, it should begin in a sedentary fashion; added physical fatigue will increase these effects.

A knowledge of the background of education, training and social requirements is a prime essential. It is often the only index for psychological rehabilitation. The modern physician has learned that a true history can be got only by listening to the patient's full story. This is how he will sift any factors that predisposed to the first clinical illness from those due to the stresses of diagnosis and treatment. Many patients require kindly consideration of their fears of insecurity in working and earning capacity that very often lie behind

(Continued on Page 61)

J. ARNOLD BARGEN, M.D.
President, Minnesota State Medical Association

President's Letter

TO: MEMBERS OF THE MINNESOTA STATE MEDICAL ASSOCIATION

We are now in the second century of the activities of the Minnesota State Medical Association, an organization that has been working tirelessly for the greater good and the better health of the people of Minnesota and the nation. This association has been in the forefront of medical progress and organization for many years, and to serve as its president entails unusual opportunities and obligations. I am proud to have been selected as its spokesman for 1957.

While the office of president has carried with it the esteem of medical men of the state, it has also demanded of the physician so honored a selfless dedication to the highest ideals of a noble profession. My predecessors have given unselfishly of time and effort to uphold the fine tradition and to advance the aims of our association.

I have often been amazed at the sacrifices made by the men who carry on the activities of this organization. They serve without thought of remuneration. Some give up many Sundays to attend meetings of the Council, where discussions may last all day and may continue on into the wee hours of the morning. In winter, this may entail 200 or 300 miles of hazardous travel; in summer, it may mean the sacrifice of a nice summer Sunday for recreation, possibly the only day of the month available for that purpose.

The Council meets regularly four times a year and in special session at least two or three times a year. Each meeting requires a full day, or more, of the nine councilors, the four delegates to the American Medical Association, the president, the vice president, the secretary, the treasurer, the speaker of the House of Delegates, various committee members, the executive secretary and his associates, and those appearing before the Council with their grievances or reports.

In addition, meetings of committees occur at various times throughout the year, usually in the evening, and require physicians to drive to St. Paul from all parts of the state, with sacrifice of time and energy. Yet those appointed to committees serve devotedly the task of advancing the health of the people of Minnesota.

The committees for 1957 have been appointed. The members of these committees are privileged to help solve the problems that face nearly 4,000 physicians in their efforts to provide high-quality medical care for the people of our state. Attendance at committee meetings is very important and requires personal sacrifices, so that no one unwilling to make these sacrifices accepts a committee appointment. It certainly speaks well for the profession when, in spite of the sacrifices required, physicians all over the state cheerfully accept such committee appointments and seem eager and willing to serve.

The honor and privilege to serve as the leader of such a devoted group of men and women come to only one physician a year. Naturally, then, he desires and needs all the help and advice he can get from all the physicians of the state to the end that the health and well-being of the people may be enriched and that the respect of others toward the members of our profession may rightly be enhanced.

To these ideals, with your help, I shall devote myself.

A large, elegant handwritten signature in dark ink, reading "J. M. Bergen". The signature is fluid and cursive, with a large loop at the end.

George Earl, M.D., Chairman

MEDICARE PLAN LAUNCHED IN DECEMBER

The military dependents' medical hospital care program went into operation December 7, 1956. Information was sent out to all members of the Minnesota State Medical Association and as further material is released, it will be passed on. The government still must settle on proper identification procedures and will be publishing a "Nomenclature of Procedures" booklet. Questions on the program may be referred to "Medicare," Minnesota State Medical Association, 496 Lowry Medical Arts Building, Saint Paul, 2. For Minnesota, Mutual of Omaha will be the fiscal agent handling hospital bills.

Anticipating many questions arising from the Medicare program, the Office for Dependents' Medical Care (ODMC) has issued several communications:

1. *Identification.*—Military dependents may submit as identification their post exchange card, the combined post exchange-commissary-military medical care card, or the standard military dependents' identification card. After July 1, the only identification honored will be a special Defense Department Medicare card.

2. *Payment for Drugs.*—ODMC says there are no plans for authorizing payment for drugs, medicinals or other medical supplies except those furnished while hospitalized or those administered directly by a physician.

3. *Claim Forms.*—The Government Printing Office is turning out large quantities of the claim form titled "Statement of Services Provided by Civilian Medical Sources" and they are being sent to the states as rapidly as possible. The State Medical Association will be glad to furnish extra claim forms to physicians on request. They are to be filled out in triplicate, one for the physician's file, and two to be sent to the state office for processing.

ODMC also stresses that it is intended that civilian medical care under the program be comparable to that provided in armed services facilities. Physicians participating will receive payment for their usual charges to their patients.

AMA LEGISLATIVE MACHINERY SUMMARIZED

A Senate subcommittee recently heard a detailed explanation of how the AMA conducts its legislative work. Senator Edward J. Thye (R., Minn.) was a member of the committee which conducted the hearing. Outlining the AMA operations were Dr. David B. Allman, AMA president-elect; Dr. Cyrus Maxwell, assistant director of the AMA Washington office; C. Joseph Stetler, head of the AMA law department and James W. Foristel, Washington office legal adviser.

The AMA spokesmen made these points:

1. The AMA takes no part in partisan fund-raising or other partisan activities.

2. The House of Delegates establishes Association policy, but if the time factor makes this impossible, the Board of Trustees is empowered to make decisions.

3. Information is sent to all state societies on national legislative problems and their support asked. There is nothing compulsory about it, however.

4. The Washington office does not keep a "box score" of lawmakers' general voting records, sending out this type of information only if asked.

5. Of the total AMA budget, not more than 2.5 per cent is spent on legislative efforts.

CIVIL SERVICE WORKING ON NEW FEDERAL HEALTH PLAN

The Civil Service commission is making a new effort at developing a federal employees' health insurance plan, one that will combine features of both basic and major medical expense coverage. Some officials believe that this time, after repeated failures, a plan can be worked out that will be acceptable to employees' unions, commercial companies and Blue Cross and Blue Shield. An administration proposal for catastrophic illness coverage failed to get through the last Congress because of objections from some unions and the non-profit plans. A previous attempt at a plan for basic coverage also failed to get off the ground.

In the event that a bill combining the best

features of both approaches is agreed on, Congress may enact a law by next July, according to the more optimistic officials.

The House Civil Service Committee expects to receive in several weeks, a report from the General Accounting Office on estimated costs of administering a payroll deduction plan for basic medical coverage. The report was requested last summer by Chairman Tom Murray after the administration's catastrophic coverage bill was not acted on. The GAO queried eleven prospective carriers, commercial and non-profit, on what they felt agencies would have to do under a payroll plan. GAO then drafted criteria for discussion among the various agencies.

The American Federation of Government Employees has proposed a "package" program which would include these features: (1) a federal employee would be permitted to buy both basic and major medical coverage through any one of a number of carriers providing the medical plan met certain government criteria, (2) the government would not set up or operate any health insurance plans of its own, and (3) employee and government would share equally in payment of premiums which would be handled through payroll deductions.

FEBRUARY SELECTIVE SERVICE CALL LARGEST IN TWO YEARS

Selective Service plans to call up 450 physicians in February, 250 of them for the Army and 200 for the Air Force. This is the largest single call since the Army, Navy and Air Force took 1,275 men in March, 1955.

The doctor draft extension bill is scheduled to expire July 1 and the Defense Department has indicated it would not ask for another extension.

RISE IN HOSPITAL ADMISSIONS INDICATED

Almost three times as many Americans are admitted to hospitals today as were twenty years ago. Six out of every 100 Americans were hospitalized in 1935, but in 1955, 13 out of every 100 were admitted, with further increases predicted for the future. The American Hospital Association reported that in 1955, U. S. hospitals spent \$5,594 billion to care for patients and newborn infants compared to \$5,229 billion in 1954. The non-profit general hospitals which care for the great majority of the acute-short term cases

in the nation, spent an average of \$25.15 a day for the care of each patient. This represented an increase of \$1.37 over 1954.

Hospital expenses continued to rise, reflecting the increase in payrolls and the increased cost of supplies and equipment. Sixty-four per cent of hospital expenditures was for payroll.

STATISTICS ON PHYSICIANS AND NURSES RELEASED

The world now has 1,200,000 physicians, and the 595 medical schools of eighty-five countries turn out between 50,000 and 60,000 new doctors each year according to a recent survey. The doctors, however, are unevenly distributed among the world's 2,500 million people. Fourteen countries have one doctor to serve up to every 1,000 people, but 222 countries have only one doctor for every 30,000 inhabitants or more.

A survey released by the American Nurses Association reports that 28,000 more professional nurses are at work today in this country than were two years ago. The increase is due to a variety of factors which include the higher rate at which married nurses are returning to the profession, and the increase in the number of part-time employees.

LEGAL MEDICAL MATTERS

Close Cooperation Between AMA and ABA

Indications of closer co-operation between medicine and the law will undoubtedly lead to the successful accomplishment of many objectives which are common to both physicians and attorneys. There have been a number of joint meetings between AMA and American Bar Association groups in recent months. At a fall meeting in Baltimore, Dr. Ernest Hammes, Saint Paul, participated in a panel on the subject of impartial medical testimony.

AMA-ABA Action on Jenkins-Keogh Bill

Vigorous action is being organized by the American Bar Association in support of a new bill—similar, but not necessarily identical to the 1955 Jenkins-Keogh Bill—for introduction in the 85th Congress this month.

This bill was introduced to help all self-employed people set aside part of their earnings for retirement. However, it died in the Ways and Means Committee.

The Physician as a Medical Witness

In a recent article entitled "You, Doctor, Will Be A Witness," C. Joseph Stetler, head of the AMA law department, suggests that the legal profession become more active in familiarizing the doctor with courtroom procedure and the "do's" and "don'ts" which should govern a medical witness.

He specifically suggests that the physician called as a witness "fear nothing about court procedures, that there is no real magic about testifying." He also says, "don't testify as an expert unless you are satisfied that you are qualified in the area of specialization involved." A third suggestion is "do not neglect to inform your patient's attorney of all unfavorable as well as favorable facts" and to "be courteous and to tell the truth without reservation or exaggeration." He adds that a physician should "not be smug; a modest attitude is much more impressive." Also, the physician should not regard it as an admission of ignorance to indicate that his opinion is not conclusive." Nor should the medical witness use terminology "which will not be easily understood; nor should he lose dignity in testimony, or lose his temper."

U. S. STEEL OFFERS NEW MAJOR MEDICAL COVERAGE

U. S. Steel's Group Insurance Plan for its salaried employes not entitled to compensation for overtime has been broadened to provide protection against costs of serious accident or prolonged illness that could be financially catastrophic. The new major medical expense coverage pays 80 per cent of a broad range of medical, surgical, laboratory, nursing, therapeutic and pharmaceutical costs that may be incurred by an eligible employe or his dependents beyond the basic surgical-hospital benefits previously provided in the Group Insurance plan. These benefits have also been liberalized.

SURVEY REPORTS OF INTEREST TO PHYSICIANS

The Doctor's Investment Woes

An investment house recently submitted an analysis of the doctor as an investor. It concluded that the "keen analytical mind of the examining room does not necessarily carry over into financial matters." An investment counselor who has handled doctors' financial affairs for many years

stated that "the typical doctor tends to plan wisely from the standpoint of a good life insurance program, and often a good annuity program, but then he's likely to scatter sums on speculative issues, many in the penny class, or to tie up sizable amounts in conservative mutual funds." He adds that a good investment program for a physician is "one that is custom-tailored to the individual's investor's needs, to meet a clearly-defined objective. "For instance," adds the investment counselor, "an older physician with a larger income might require blue-chip securities with a steady yield. A younger man, with a longer earning expectancy and lesser responsibilities, might be better off with growth stocks that have a deferred pay-off." He concludes by stressing the fact that "reliability in an investment firm is vital, and membership in the New York Stock Exchange is a good index to reliability."

Income Comparison Survey Results

A recent survey of representative communities all over the country reports on a "basic shift in our traditional income patterns." The most important general fact which stands out is that almost everybody except the farmer is making more money than ever before. The average total income of U. S. families exploded upward by a full third between 1947 and 1955 . . . from \$4,130 to \$5,520. Living costs also rose, but even allowing for this, the average family enjoyed a real dollar gain in that period of more than \$650 a year. The survey goes on to report that "doctors have come up as the most conspicuously prospering group in our country . . . the baby doctors in particular because of our booming birth rate. Among others who are doing outstandingly well are bricklayers, factory foremen and sales experts such as advertising men. On the other hand, the new relative poor include bank tellers, policemen . . . and income tax collectors!

FACTS ON MEDICAL EDUCATION

AMEF State Chairmen to Meet

The sixth annual meeting of state chairmen of the American Medical Education Foundation will be held in Chicago on January 27. At the opening session of the House of Delegates in Seattle, the AMA announced that it is making another gift of \$125,000 to the AMEF, bringing to \$343,000 the total amount which the AMA has contributed to the Foundation this year. The

(Continued on Page 59)

AMERICAN MEDICAL ASSOCIATION

Report on Actions of the House of Delegates

Medical ethics, veterans' medical care, radioactive isotopes, continuance of the AMA interim session, hospitalization for patients with alcoholism and a report of the Committee on Medical Practices were among the wide variety of subjects acted upon by the House of Delegates at the American Medical Association's Tenth Clinical Meeting held November 27-30, 1956, in Seattle.

Dr. Edward M. Gans of Harlowton, Montana, was announced at the opening session Tuesday as the 1956 General Practitioner of the Year. The annual award, carrying with it a gold medal and a citation, is presented to a family doctor selected by a special committee of the Board of Trustees for outstanding community service. Dr. Gans, who is eighty years old, has practiced medicine for fifty-one years and has been in the Harlowton area for the past forty-four years.

Strongly condemning government intervention in medicine, Dr. Dwight H. Murray of Napa, California, AMA President, told the opening session that "the medical profession, along with business and industry, is caught between those who desire to promote sound government programs and those who desire even more intensely to perpetuate party politics. Unfortunately, in recent years a benevolent federal government appears more attractive to the voting public than the preservation of individual freedoms. Medicine must do its utmost to reverse this trend."

Total registration at the end of the third day of the meeting, with half a day still to go, had reached 5,191, including 2,738 practicing physicians and 2,453 residents, interns, medical students, nurses and guests.

Medical Ethics

Subject of greatest interest at Seattle was the proposed ten-section revision of the Principles of Medical Ethics originally submitted at the June, 1956, Annual Meeting in Chicago, where final action was deferred until the Seattle session. The proposed short version of the Principles was re-submitted this week, with some changes based on suggestions received since last June by the Council on Constitution and By-Laws. The House of Delegates, however, decided to refer the matter back to the Council on Constitution and By-Laws for further study and consideration. The reference committee report adopted by the House included the following statements:

"Careful consideration was given to the Preamble and the ten sections of the proposed principles. The Preamble and seven of the ten sections appear to be acceptable in their present form.

"Sections 6 and 7 were not acceptable as presented

either to the group which appeared at the hearing or to your reference committee.

"Out of the general discussion the reference committee received the crystallized opinion that at least four areas needed more specific attention in Sections 6 and 7. These are: (1) division of fees; (2) the dispensing of drugs and appliances; (3) the corporate practice of medicine; (4) greater emphasis concerning the relationship between physicians and patients.

"In addition, the reference committee felt that the wording in Section 10 could be improved if amended to read as follows:

"The responsibilities of the physician extend not only to the individual but also to society and deserve his interest and participation in activities which have as their objective the improvement of the health and welfare of the individual and the community."

"In view of the above your reference committee believes that the proposed Principles of Medical Ethics should be referred back to the Council on Constitution and By-Laws for further study and consideration of the above stated principles.

"In the short space of time at our disposal and in view of the importance of the subject, your reference committee did not deem it wise to attempt to properly phrase these concepts.

"We would also recommend that if possible this study be completed at least six weeks prior to the June session and that the new version be published in *The Journal* in order that all interested physicians might have an opportunity to comment thereon."

Veterans' Medical Care

The House revised AMA policy on veterans' medical care by endorsing in principle the following paragraph suggested by the Council on Medical Service:

"With respect to the provision of medical care and hospitalization benefits for veterans in Veterans Administration and other federal hospitals that new legislation be enacted limiting such care to veterans with peacetime or wartime service whose disabilities or diseases are service-incurred or aggravated."

This action eliminates the temporary exceptions which were made in the June, 1953, policy regarding wartime veterans who are unable to defray the expenses of necessary hospitalization for non-service-connected cases of tuberculosis or psychiatric or neurological disorders. In making the policy change, the House approved this supplementary statement:

"We recognize the laws and administrative extensions of the law that are now in operation. We feel that under the circumstances it will be to the best interests of the public in general, and veterans in particular, if medical societies, county and state as well as national, develop committees to assist in guaranteeing VA hospital admission to service-connected cases. While the present law exists, we should help assure that veterans whose illness constitutes economic disaster will not be displaced by those suffering short-term remediable ills which, at the worst, constitute financial inconvenience."

In another action concerning veterans, the House passed two resolutions condemning as unlawful the practice of Veterans Administration hospitals which admit patients who are covered by workman's compensation insurance or by private health insurance and which render bills for the cost of their care. Both resolutions requested the AMA to take action to bring about a discontinuance of such practices by VA hospitals, and one of them instructed the Association Secretary to obtain from each state testimony or records of each known case that violates VA Reg. 6047-D1.

Radioactive Isotopes

The House rescinded the June, 1951, action, which limited the hospital use of radium and radioactive isotopes to board-certified radiologists, by approving a new policy statement which says:

"(1) In any hospital in which a patient is to receive radium or the products of radium or artificially produced isotopes, there should be a duly appointed Committee on Radium and Artificially Produced Radioisotopes of the hospital professional staff. This committee should include, but not necessarily be limited to, the following qualified physicians: a radiologist, a surgeon, an internist, a gynecologist, a urologist and a pathologist. This committee should have available such competent consultation of other physicians and scientific personnel as may be required by it. Where this is not practicable, the hospital staff should consult the nearest Committee on Radium and Artificially Produced Radioisotopes.

"(2) In any hospital, the use of radium or its products and artificially produced radioactive isotopes for diagnostic or therapeutic purposes shall be restricted to qualified physicians so judged by the Committee on Radium and Artificially Produced Radioisotopes of the professional staff to be adequately trained and competent in their particular use.

"(3) It is recommended that procurement, storage, dosimetry control and inventory of all radioactive isotopes for the use of the hospital staff and radiological safety control be centralized, and, where administratively possible, centralization be located in the Department of Radiology.

"(4) It is recommended that the Board of Trustees assign to the appropriate council or committee the continuous study of the problems of radiological safety control in the use of radium and its products and artificially produced radioactive isotopes for diagnostic or therapeutic purposes."

Clinical Meetings

Rejecting a resolution which recommended discontinuance of the interim sessions, or clinical meetings, the House adopted a reference committee report which said:

"We believe that the interim sessions should be continued because of the public relations value of these meetings to the Association and the educational value to physicians and the general public in the various geographical areas involved.

"It is the suggestion of the reference committee that maximum attention be given to these potential benefits in selecting a city for the interim meeting.

"It is our further recommendation that the Board of Trustees consider the advisability of holding an

Interim Meeting of the House of Delegates in Chicago each November or December and an Interim Scientific Session in November or December of each year in different parts of the United States. The reference committee suggests that the views of the Board of Trustees in this regard be reported to the House of Delegates next June."

Hospitalization for Alcoholics

To implement educational approaches to the problem of alcoholism, the House approved a statement submitted through the Board of Trustees by the Council on Mental Health and its Committee on Alcoholism. The House also recommended that the statement be brought to the attention of the Council on Medical Education and Hospitals, the Joint Commission on Accreditation of Hospitals and the American Hospital Association. It includes the following:

"The Council on Mental Health urges hospital administrators and the staffs of hospitals to look upon alcoholism as a medical problem and to admit patients who are alcoholics to their hospitals for treatment, such admission to be made after due examination, investigation and consideration of the individual patient. Chronic alcoholism should not be considered as an illness which bars admission to a hospital, but rather as qualification for admission when the patient requests such admission and is co-operative, and the attending physician's opinion and that of hospital personnel should be considered. The chronic alcoholic in an acute phase can be, and often is, a medical emergency."

Committee on Medical Practices

In approving a progress report of the Committee on Medical Practices, the House amended one of its directives to read as follows in order to remove any legal objections:

"The AMA representatives on the Joint Commission on Accreditation of Hospitals be instructed to stimulate action by that body leading to the warning, provisional accreditation, or removal of accreditation of community or general hospitals which exclude or arbitrarily restrict hospital privileges for generalists as a class regardless of their individual professional competence where such policies adversely affect the quality of patient care rendered. Any action taken should be only after appeal to the Commission by the county medical society concerned."

The House also approved a recommendation by the Committee on Medical Practices that a study group be formed to consider the best background preparations for general practice and it urged that such action be implemented as soon as practicable.

Miscellaneous Actions

Among many other actions on a wide variety of subjects, the House of Delegates also:

Urged the widest possible publication and distribution of Dr. Murray's *presidential address* at the opening session.

Pledged the full support of the Association's initiative and energy to President Eisenhower's

people-to-people program as a means of promoting understanding, peace and progress.

Directed the Board of Trustees to continue its investigation of the practicability of developing a *statement of AMA policies* and to arrange for the periodic publication of revised versions of such a policy statement.

Commended the objectives of the American Association of *Medical Assistants* and its sincere desire to work closely with the medical profession in improving medical service and medical public relations.

Noted with pride the good work being done by the 74,348 members of the *Woman's Auxiliary*, as reported to the House by Mrs. Robert Flanders, President.

Directed the Councils on Pharmacy and Chemistry and on Foods and Nutrition to conduct a joint study of all presently available information concerning the *fluoridation of public water supplies* and to present a documented report of findings and recommendations at the December, 1957, meeting.

Urged all physicians to participate actively in the formulation of medical policy for *prepaid medical care plans* which are under physician direction or sponsorship.

Changed the By-laws to extend *service membership* to reserve officers on extended active duty with the defense forces and the U. S. Public Health Service.

Changed the By-laws relating to *transfer of membership* so that an active or associate member of the Association who moves his practice to another jurisdiction may continue his AMA membership by applying for membership in the constituent association in his new jurisdiction, subject to a two-year limit on approval of his application.

Changed the By-laws so that the *election of officers* may take place at any time on the fourth

day of the annual session, instead of being restricted to the afternoon of that day.

Passed a resolution calling for the American Medical Association to join with the American Hospital Association and the American Institute of Architects in their proposed *study of hospital design and construction*.

Approved the principle of a voluntary reduction in the self-assigned *quota of interns* as printed in the 1956 handbook of the National Intern Matching Program.

Instructed the Board of Trustees to accentuate co-operation between the American Medical Association and the American Bar Association to the end that a bill of the *Jenkins-Keogh* type be enacted at the next session of Congress.

Citation and Contributions

At the Tuesday opening session, Dr. Dwight H. Murray, on behalf of the American Medical Association, presented a special citation to Ciba Pharmaceutical Products, Inc., for "the service it has performed to the medical profession and to the nation through its weekly television series, 'Medical Horizons'." At the same session, the American Medical Association and four of its constituent societies—California, Arizona, Utah and New Jersey—contributed nearly \$300,000 to the American Medical Education Foundation for aid to the nation's medical schools. The AMA announced another gift of \$125,000, bringing this year's total contribution to \$343,000. The amounts presented by the four states were: California, \$132,981; New Jersey, \$25,000; Utah, \$11,870, and Arizona, \$3,695.

practicing physicians of the nation have contributed nearly \$6 million to the Foundation since it was founded in 1951.

More Women Studying Medicine

The AMA reports that during the academic year 1955-56, 1,573 women were studying medicine in the seventy-six approved four-year medical schools in the United States. This was a 2.3 per cent gain over the previous year. The Woman's Medical College of Pennsylvania had the

highest enrollment of any school . . . 182. The medical schools of Columbia University and the State University of New York each enrolled 40 women or more.

States Producing Most Medical Students

Forty per cent of all first-year students in the nation's seventy-six approved four-year medical schools comes from six states: New York, Pennsylvania, California, Ohio, Illinois and Texas. Also, nearly 38 per cent of the nation's medical schools are located in these same six states.

Medical-Legal Opinions

By JULE M. HANNAFORD, Legal Counsel
Minnesota State Medical Association

With this issue, MINNESOTA MEDICINE initiates a new series of legal opinions of interest to the physicians of this state. These opinions were prepared by Jule M. Hannaford, legal counsel for the Minnesota State Medical Association. Mr. Hannaford is affiliated with the firm of Dorsey, Owen, Barker, Scott and Barber, Minneapolis.

NEW TAX REGULATIONS

Many tax-exempt organizations have purchased annuity contracts for their employees without going through the formality of setting up a pension plan qualified under the Internal Revenue Code. Tax-exempt (charitable) hospitals have been among the organizations which have done so. In many cases, they have done so for the benefit of physicians on their staffs, either on a full-time or a part-time basis. For some time it has been thought that the persons for whom the annuity contracts were purchased did not have to include in their gross income for income tax purposes the premiums paid on these annuity contracts by the tax-exempt organizations. On September 24, 1956, the Treasury Department issued new regulations which may affect every physician for whom an annuity contract has been purchased by a tax-exempt organization. The regulations provide that the physician need not include in his gross income for income tax purposes the premiums paid on such annuity contracts, provided the purchase of the annuity contract is merely a supplement to past or current compensation. The regulations then go on to describe what is meant by the phrase "a supplement to past or current compensation" in the following words:

"* * * One of the pertinent facts to be taken into consideration is the ratio of the consideration paid by the employer for an employee's contract to the amount of his past or current compensation. For example, if the annual premium paid for an employee's contract is \$1,000 and his annual salary is \$10,000, the ratio indicates that the premium paid for the contract is merely a supplement to the employee's current compensation. If, however, an employee receives no current compensation, or the annual premiums paid for his annuity contract approximate his annual salary, the amount paid for his contract will be considered to be current compensation and taxable to the employee in the year in which it is paid by the employer. Other pertinent considerations are whether the annuity contract is purchased as a result of an agreement for a reduction of the employee's annual salary, or whether it is purchased at his request in lieu of an increase in current compensation to which he otherwise might be entitled. In such cases, the amount paid for the contract shall also be considered to be current compensation."

Any physician for whom an annuity contract has been purchased by a tax-exempt organization

should, therefore, consult with his attorney on this problem before filing his Federal income tax return for the year 1956.

STERILIZATION

The sterilization of persons who are not inmates of institutions raises legal problems for the physician.

Therapeutic.—The first problem to be considered is that in connection with therapeutic sterilization, i.e., sterilization for the protection of the patient's health. There is little doubt under the decision of the Minnesota Supreme Court in the case of *Christensen v. Thornby*, 192 Minn. 123 (1934) that a sterilization performed in Minnesota upon a person is lawful where there is medical necessity for the operation. The court stated specifically in that case that sterilization, when a medical necessity, is not against the public policy of the state and is not therefore illegal.

There are no Minnesota decisions with respect to what consents are legally necessary before a therapeutic sterilization may be performed. However, the general rule of law is that a woman of mature years and sound mind is capable of authorizing an operation upon herself even though she is married and that the consent of her husband thereto is not needed. There should be no reason to distinguish on this score between a therapeutic sterilization and any other type of operation. However, because of a husband's particular interest in any sterilization and because the mental capacity of a woman contemplating sterilization might be questioned, we would strongly recommend that no therapeutic sterilization be performed by a physician on a woman unless her husband consents thereto.

There is no legal requirement that one or more medical consultants be called in before a physician performs a therapeutic sterilization. Nevertheless, because a physician's judgment as to medical necessity may be questioned in subsequent litigation, we would strongly recommend that where practicable at least one other physician be called into consultation before a therapeutic sterilization is performed.

Nontherapeutic.—The second aspect of this problem relates to what might be called nontherapeutic sterilizations. Such sterilizations might logically be divided into two types, i.e., those justified on social or economic grounds and those justified on no grounds except a desire of the patient to avoid pregnancy. Despite such possible sub-division of the problem, the courts up to the present time have recognized no such distinction and so both types will be considered together.

The problem in connection with such a sterilization is whether or not it is illegal even if done with the consent of both the husband and wife. At least three states have by statute declared nontherapeutic sterilizations illegal and one appellate court has reached the same conclusion without the aid of a statute. The theory behind both the statutes and the court decision is that the state has a sufficient interest in the perpetuation of its people to prevent sterilization when not required by medical necessity.

* Minnesota has no statute and no reported court decision on this question. The Minnesota Supreme Court, in the case of *Christensen v. Thornby*, *supra*, specifically refused to answer the question. Minnesota does, however, have statutes which prohibit abortion unless medically necessary, Minn. Stats. Sections 617.18 to 617.22, and which prohibit the selling or giving away of contraceptives, Minn. Stats. Section 617.25 (the contraceptive statute, incidentally, has no exception for medical necessity). These statutes could easily lead a court to conclude that the public policy of this state makes illegal any sterilization not required by medical necessity. We are in no position to predict how the Minnesota courts will decide this question which raises many religious, social and economic emotions.

If the Minnesota courts should decide that nontherapeutic sterilizations are against public policy and therefore illegal, a physician who performed such an operation would be faced with questions of both criminal and civil liability.

With respect to the criminal liability aspect, he might be prosecuted under the criminal law prohibiting a mayhem or the criminal law prohibiting an assault and battery. We are, however, of the opinion that the chances of success of such a prosecution, where both the husband and wife have consented to a nontherapeutic sterilization, is small because, to constitute either crime in Minnesota, the act must have been done with an intent to do harm. *State v. Hair*, 37 Minn. 351.

With respect to the civil liability aspect, a physician who performed a nontherapeutic sterilization with the consent of both the husband and wife might, notwithstanding such consent, be sued for damages on the theory that a consent to perform an illegal operation is void and therefore no bar to a suit. In the case of *True v. Older*, 227 Minn. 155, the Minnesota Supreme Court

specifically refused to decide whether consent to a nontherapeutic abortion barred recovery by the person who consented thereto. We therefore cannot predict how the Minnesota courts will decide this question.

If, despite the admittedly unsatisfactory status of the physician's potential liability, a physician decides to perform a nontherapeutic sterilization, we strongly recommend that he secure a written consent from both the husband and wife. We further recommend that the signing of such a consent should follow a complete explanation of the results of the operation to both husband and wife and a cooling-off period in which both can consider the problem further. We further recommend that both husband and wife should be told that at least some types of sterilization operations are not always completely successful. We make this recommendation particularly because in the case of *Christensen v. Thornby*, *supra*, the physician was sued because a pregnancy resulted after a sterilization of the husband. While such explanations and written consents may not in the final analysis save the physician from legal liability, they will place him in a much better position legally to defend any action that may be brought against him.

If a nontherapeutic sterilization is performed, there is no legal requirement that consultants first be called in. Moreover, we can see no useful purpose that their testimony could serve if a physician were later sued for performing such a sterilization.

REHABILITATION IN PULMONARY TUBERCULOSIS

(Continued from Page 51)

the superficial resentment of authority in nurses and doctors. These fears explain also why the patient-worker is often difficult in the early days of vocational training, why he is often restless in his anxiety to go too fast, or difficult to rouse out of his apathy to his new conditions. He has not learned that the first step in overcoming his disability is to accept it, and so will often ask for a change from the workshop which he blames for his disappointments.

The physician need not be a neuro-psychiatrist, but if he relies entirely on a fixed routine of anti-bacterial treatment, however good it may be, or believes perfection lines in the employment of the latest mechanical aids, he may preserve the lives of his patients but will not renew them.

History of Medicine in Minnesota

THE HISTORY OF MEDICINE IN POLK COUNTY

J. F. NORMAN, M.D.
Crookston, Minnesota

In compiling a history of the early doctors in the Red River Valley, thought should be given to the Valley itself; its origin, and its changes through time.

The Red River Valley had been in the process of formation for untold ages. The present prairie part of the valley of Polk County was covered by a salt sea in the Cretaceous Age. Very little change took place either in the soil or on the surface during these millions of years of time. This inland sea extended from the Gulf of Mexico on up into the Arctic Ocean. In some places the sediment laid down shows up either in cliffs or rocky bluffs, such as the Missouri Couteau in the Dakotas, and in wells drilled on the east side of the Red River of the North. In the course of time the crust of the earth beneath this area began to rise, and eventually this sea disappeared. Then came a change with the climate becoming cooler. The earlier period was comparatively warm. Now, heavy snowfall was not thawed during the ensuing seasons and a glacier formed some hundreds of feet thick. This glacier moved south from the west of Hudson Bay and moved down what is now the Valley of the Minnesota River, cutting out the soil and denuding the north land of much moveable clay and other detritus. After some thousands of years, another change of climate brought about a disappearance by thawing of this great ice field. Meanwhile, the glacier had brought down a tremendous amount of till, clay, gravel, et cetera. The highlands of the north were ground to powder and deposited on the floor of the valley.

The next change was the thawing of the great glacier which, of course, started in the south, and caused the glacier to retreat northward, leaving a tremendous lake of fresh water, the great Lake Agassiz. After some thousands of years it finally broke down its northern ice barrier and drainage followed much in the present manner. Earlier, the water of the lake had flowed down through what is now the Minnesota Valley. The lake-bottom was gradually built up with silt which had been in suspension in the water of the lake, leaving a very fine soil when the water had disappeared. This took place comparatively recently geologically, possibly less than fifteen thousand years ago. It made this area one of the most fertile in the world, and one of the greatest agricultural valleys on earth.

No one lived here for a long while, but in time the Indians came. They were purely a hunting and fishing people who made no change in the valley. It was never very well settled by the Indians and they remained food gatherers instead of food producers; they managed to exist from day to day.

The first Europeans to visit what is now Polk County came from the East. They were traders, explorers and missionaries, probably French. They came to buy furs and to visit the savages, and later, to lay claim to the country for France. Radisson and DesGroselier came to Minnesota in 1658-1660 and in 1661 St. Luson made similar claim to the country for France. On the other hand, the Hudson Bay Company claimed all the land draining into the Hudson Bay, which included Polk County.

Most of the men who entered the territory, and there were few, were traders and

trappers. At the time of the Louisiana Purchase very little was known as to what should be the Northern boundary of this area, and finally, after the convention of Ghent in 1818, the boundary between the United States and Canada was placed at the forty-ninth parallel. This made the present area of Polk County indisputably American soil. In the treaty of 1863, the Chippewas ceded much of their valley land to the government. This treaty was signed at Huot, near Crookston. While the treaty was being signed, the Sioux Indians were laying siege to Fort Abercrombie at the southern end of the valley, where they attempted to capture goods and cattle en-route to the treaty signing. This treaty was called the Old Crossing Treaty, because at this spot the Red River carts would ford the Red Lake River. A steamboat was launched on the Red River of the North about 1859. It came up to Fisher, but was not of much importance for Polk County. The fur companies bought and transported furs through Polk County mostly by Red River carts. Several expeditions were made overland to Pembina on the east side of the river, and this took them into Polk County. At that time some people, including General Sibley, thought that the Red River Valley would never be fit for cultivation or for agriculture; they claimed it was too swampy, too flat and too cold, but one of the early acts of the new state legislature was to establish Polk County on July 20, 1858.

The medical history of Polk County is that of the medical history and progress of the State. Physicians arrived here late but they were better educated than earlier arrivals in the State.

The history of medicine started late in Polk County as compared to the rest of the State. During the 1850's and 60's settlers had poured into Southern Minnesota after the opening of Indian land following the Treaty of Traverse De Sioux. During the years 1860-69 there were neither Indians nor whites living in what is now Polk County, although they had been here earlier, but they left no impression on the county. There was no medical care by regular practitioners, only a certain amount of care by irregular quacks and Indian medicine men. This area had its flood of settlers during the decade 1870-1880. Some doctors came in and took homesteads, while others settled in towns. Many of these early doctors, some of them suffering from tuberculosis, came to Minnesota because the climate was spoken of as being very healthy. They took up homesteads, later going into practice. Practically all of them were young, though some were married and had families. Some stayed only a very short time and moved on. Even after the county was being settled, the quality of medical care was very poor, and many of the settlers resorted to self-medication, plus patent medicine, and charms, amulets or talismans. To the Indian, all medicines were charms, and were good or poor depending on whether the spirit in the medicine was strong or weak. The settlers had some of this feeling, an example being a charm possessed by someone, which would stop bleeding, even at a distance, the charm being the reciting of some words or incantation.

The late W. A. Marin, who practiced law in Crookston, has left some good notes on his frontier life on a claim near Crookston.*

Maternal care is well described by him, because his mother was an intelligent woman who acted as a midwife for her neighbors. He tells of a wagon driving up at night and his mother going out, to return some days later; some neighborhood wife had been helped at the birth of her child. An example of such help by a practical nurse was that of Grandma Tierney, who was an early pioneer. Her active life dated from 1870 to 1885. She would not accept payment for her help, and would insist on a doctor being present if she thought the labor was making slow progress. After delivery, she cleaned up the baby and laid out the baby's freshly

*This account is not published, but is preserved in the Crookston Public Library.

prepared clothes, then she asked for a piece of white "linen," had it put in the oven until it was browned, and she covered the navel with it. Therefore there were few infections of the cord stump. Many of these practical helpers were clean, using soap and water, and there was a low infant mortality until the baby's first summer on artificial feeding, when the mortality became high. At that same time the early doctor had a high maternal mortality and prolonged morbidity, for which often he was not to blame. Some physicians were too quick to use forceps, with scant use of cleansing agents. Self-medication was common among the settlers, such as, "Cherry-Pectoral" for colds, pneumonia or "consumption." Hoods Sarsaparilla was much used. Hostetter's Bitters had quite a vogue, although much of this was made up of very poor whiskey. These drug firms put out very interesting almanacs which were welcome, and which the small boys would read from cover to cover. They learned that some of these medicines were "good for man or beast," and for a boy at a time when books were scarce, much advice on non-medical subjects was absorbed.

At this time, should a settler get a laceration from a scythe or puncture from a nail, he might call some man in the neighborhood who would lay on some talisman, magic amulet, some "holy object," salve, or even raw pork. Later there would be laudable pus and there would be applied a hot poultice of bread, milk, flaxseed or others, such as a leaf poultice, (cabbage or another leaf). Some terrible infections occurred, but at the time there was no good medical help available. At this period it was common to know of "consumption" families. Perhaps the mother was tuberculous; soon a child would come down with it, and many died. They all lived in a small house, probably, perhaps several in one room.

About the time the Red River Valley was being settled the quality of medical care improved, and the type of physician changed for the better. In 1853 a group of physicians organized the State Medical Society in St. Paul. This group set about cleaning up their own profession. One problem was to set up standards of what was or was not good medicine. They set about revising their by-laws, and they were very much concerned about the high number of irregulars with irresponsible practice. It was hard to determine whether or not a diploma was forged or stolen, as the Eastern states were full of "diploma mills."

Some of the physicians who applied for licenses to practice in Minnesota had questionable backgrounds. Most of them had diplomas which did not promise much. Perhaps they had two years of study (though later they had three years of preparation), being limited to lectures, many of them repeated from year to year.

The number of regulars exceeded the irregulars only by a small margin. Membership in the State Society was denied to anyone who could not show satisfactory evidence of his being a legal practitioner of medicine. In 1870 the Society adopted an amendment to its constitution which set up a mechanism for examining prospective applicants for membership in the Society.

This period was one of a renaissance in the medical world, and its new life was felt wherever medicine was practiced—including Polk County.

Following the Chippewa cession of their valley lands, settlers arrived in greater numbers. With the exception of missionaries of various faiths, these new settlers came to make a profit buying and selling real estate and trading in furs. Many of them came to make homes for themselves and their children, and to build up a certain amount of financial security. Settlement was not opened in Polk County until 1870-71; then the opportunity to take up land by homestead was offered. The treaty of 1863 was not ratified until April 21, 1864.

The early boundaries of Polk County were indefinite, extending from the Red River of the North to Itasca and northward to the Canadian boundary. The

county was formally organized October 21, 1872, when the newly elected County Commissioners held their first meeting. For some time, the history of the new county was the history of Crookston, early called "Red Lake River Crossing." The city was designated as county seat and this was confirmed in 1873. Meanwhile, several counties were carved out of this territory and the limits of Polk County became defined much as they are now. The new county seat grew rapidly and became better organized and an ambitious citizenship developed.

The new county soon organized a board of commissioners. Present at that first meeting and acting as clerk, was E. M. Walsh, who later in life was a friend of this writer. Later he acted as treasurer of the new county.

These new citizens were mostly from the East and were of American stock, Irish and Scotch from the Dominion of Canada, French Canadians from Quebec, and many Europeans, mostly from Great Britain, were also included.

Increasing numbers of physicians came with these settlers and they were better educated than their predecessors. Medical care continued to improve and soon the physicians in the valley became associated with the other physicians of the State through their medical society.

As mentioned, the early history of Polk County was the history, in fact, of Crookston. The population in 1875 was 150 for Crookston and 197 persons for the entire district. Very early, schools, literary societies, and a philharmonic society were established. The literary society used its surplus funds to support a circulating library which speaks well for the young county and city. They began to feel conscious of their prairie type of town, so one citizen had his house painted to indicate the end of pioneer conditions. Pigs, though, were still allowed to run around a bit, and this was hard on the citizens who planted flowers and gardens. Drinking water was taken from the Red River.

The first preaching service conducted in Crookston was held October 2, 1877, with the Rev. M. G. S. Felton of the Glydon Union Church officiating. In 1878 the population of 300 boasted one drug store, three lawyers, two physicians, and a Union Church. This church was the first organized church in Crookston.

The first report of physicians in Polk County is that of Doctors Waterman and Welch, who reported a case of smallpox in Crookston, May 2, 1879. A pest house was built and one Theodore Binder was admitted, and it was stated that he was very well taken care of. In the fall of 1879 Crookston had four doctors and one dentist.

While Crookston and the surrounding valley took an early lead in the settlement of the North—and much early progress was made—it remained for transportation to the East to be improved. A railroad reached Fosston in 1888 or 1889, giving both farmers and merchants a better chance to get goods to and from markets. Later, because of dissatisfaction with their dealings with Twin City markets, especially grain terminals and mills, there was agitation for transportation to the head of lakes and to water terminals. This resulted in extending the railroad to Duluth in 1898 with new lands being opened up and much lumber being hauled.

The eastern half of Polk County was covered with growth of hardwood for wood and lumber, rolling rich lands and many lakes: an altogether beautiful place to settle. There were fish in the lakes, deer in the woods, and—in spring and fall—geese and ducks in the lakes. Soon much of the lands were taken, mostly by Scandinavians, many of whom came directly from Europe. They were of a high type, had high ideals, were ambitious to better themselves, and rapidly built up the country.

Physicians soon followed. Many were foreigners and because they were of a later school, they brought good service to the settlers. With the coming of the Northern Pacific Railway to Crookston, transportation at Fertile was much improved and that rich area opened to farming and to better medicine. The old days of long trips of twenty or more miles to market or for transportation for crops were passing.

This area was fast becoming a region of fine farms, homes and a stable population. Farming was not big business, but was progressive, and the area became a successful productive area. Fosston and McIntosh, too, became thriving cities with capable physicians.

During the last quarter of the nineteenth century the doctors of Minnesota were in the midst of universal renaissance. The practice of medicine was regulated by the Medical Practice Act of 1883. The State Board of Health, which had its inception in 1872, was growing in stature and its supervision and help could be felt even in the outlying counties of the state, including Polk County. Emphasis was placed on preventive medicine, especially the prevention of contagious diseases and general sanitation.

Vaccination was mandatory for such diseases as responded to such immunization efforts. The men in our State Department of Health had a special problem in the great lumber camps across the northern part of the state. This affected the health of Polk County as well as the other areas in that patients would run away from lumber camps and other labor camps. They would come to Crookston, Fosston, or McIntosh, and the municipality would have the problem of giving them care, shelter and food during quarantine.

One problem with which the State Department of Health contended was the indifference, often antagonism, of the owner or the manager of such lumber camps.† The men themselves were of such a type that they did nothing to use preventive measures and would avoid vaccination or such other precautions if possible. Smallpox was the common problem. An example of this was an experience at Crookston in 1885 when a smallpox case from T. B. Walker's lumber camp, about 70 miles east of Crookston on the Clearwater River, drifted into the city. He went into the Merchant's Hotel where a physician pronounced his case smallpox. The landlord of this hotel doubted the diagnosis. He later came down with variloid. Dr. Brown of the State Board of Health was sent north and found two cases in Fosston. One man of one of the camps became delirious with the disease and is supposed to have perished in the woods.

Dr. Charles N. Hewitt, the energetic secretary of the State Board of Health, was a relatively patient man, but after putting up the dilatory practices and evasions of a village where numerous cases of "Cuban itch" were at large waiting on tables, selling goods in the stores, et cetera, he quarantined the whole village. No one, including the farmers, was allowed to enter or leave the place. The trains did not stop, but pushed off the mail and would not take on any mail. All non-immunized persons were rounded up and vaccinated and the epidemic was soon under control.

Although some of the men in this territory had the old-type training with a course of lectures and not too much clinical training, the presence of a medical school in the state after 1888 made for better medical men and better treatment. Soon University of Minnesota trained physicians who spread over the state in greater numbers to the great advantage of the people and progress was rapid.

†*"The People's Health, a History of Public Health in Minnesota up to 1948,"* by Philip D. Jordan, Minnesota Historical Society, 1953.

A few remained in practice who insisted in preparing their medicines from the crude drugs, the quality and strength of which was not standardized.

Much of a doctor's practice was in the country over poor roads, through storm and drifted snow. Many calls were at night. Roads were unmarked, and there was danger of getting off the road. For the night call, the doctor would pick up his instruments and all other material he might need and call up the livery. His driver would eventually get to the doctor's home and they would bundle into the cutter, the doctor dressed in high overshoes, perhaps with a pair of mackinaw trousers over his regular clothes, an overcoat, and over that, a fur-lined coat and a heavy fur cap. He carried the little black leather bag containing the materials above mentioned. The cutter had a buffalo robe and its seat was covered with blankets, with another blanket beneath the robe. A foot-warmer was set on the floor of the cutter. Snow would blow and obscure the road and at some spots the doctor would hold the reins while the driver went ahead on foot to spy out the crossing. All this preparation was necessary because these sick calls were made at a distance of ten to twenty miles, often in bitter winter weather.

To be feared was the newly-drifted snow through which the horses would not be able to travel. Then, the doctor and driver would unhitch the team, get them out of the drift, pull the cutter out by hand, hitch up the team and on to the patient—all this in the dark and very cold weather with drifting snow and poor visibility. He might have to stay all night at the home of the patient and drive back to town in the morning, very tired but with little opportunity to rest during the day. Next fall he might receive as part payment, a quarter of beef or a turkey or a pig. These men went on without complaining. Part of the doctor's remuneration was a cordial "Hello, Doc!" when he met his patient on the street.

Now began an era when living out on the prairies presented less risk of disease and death. Typhoid, which had been endemic, gradually was reduced in incidence with the help of an alert State Board of Health. Vaccination was increased, cutting down the number of cases of smallpox per year. Diphtheria was being attacked by the physicians, with marked decrease in cases due to earlier and better laboratory diagnosis. The physician had much education of the public on his hands as it was difficult to get the cases early; the antitoxin and dosage had to be adjusted as more was learned about it. People also learned that tuberculosis was infectious and soon these cases were isolated.

(To be continued in the April issue)

Meetings and Announcements

STATE

MINNESOTA STATE MEDICAL ASSOCIATION, 104th annual meeting, Saint Paul, May 13, 14 and 15, 1957.

Mediclinics of Minnesota, Fort Lauderdale, Florida, March 4-14, 1957. For information write 516 Medical Arts Building, Minneapolis 2, Minnesota.

NATIONAL

American College of Radiology, annual meeting, Chicago, Illinois, February 8.

Alumni Postgraduate Convention, College of Medical Evangelists School of Medicine, Los Angeles, California, March 10-14. Managing Director, Alumni Postgraduate Convention, 316 North Bailey Street, Los Angeles 33, California.

American College of Surgeons, sectional meeting, Hotels Lowry and St. Paul, St. Paul, Minnesota, April 8-10, 1957. Write Dr. H. Prather Saunders, Associate Director, American College of Surgeons, 40 East Erie St., Chicago 11, Illinois.

American Congress of Physical Medicine and Rehabilitation, thirty-fifth annual scientific and clinical session, Los Angeles, September 8-13, 1957.

Centennial Exposition, Academy of Medicine of Cincinnati, Health Museum, Cincinnati, Ohio, February 27-March 5, 1957.

Centennial Exposition, 100th anniversary of the Academy of Medicine of Cincinnati, Music Hall, Cincinnati, Ohio, February 27-March 5, 1957.

Central Surgical Association, Chicago, Illinois, February 21-23. Dr. Charles D. Branch, Secretary, 102 North Street, Peoria, Illinois.

Chicago Regional Committee on Trauma, American College of Surgeons, course on fractures and other trauma, April 10-13, 1957, John B. Murphy Auditorium, 50 East Erie Street, Chicago, Illinois. Dr. Sam Banks.

College of Medical Evangelists School of Medicine, 1957 Alumni Postgraduate Convention, Los Angeles, California, March 10-14, 1957. Refresher courses, March 10 and 11, giving Category I credit, American Academy of General Practice. Write: Managing Director, Alumni Postgraduate Convention, 316 North Bailey Street, Los Angeles 33, California.

First American Post-Graduate Assembly in Fertility and Sterility, New York Medical College-Metropolitan Medical Center, May 18-31. Dr. Ralph E. Snyder, Dean, New York Medical College, 1249 Fifth Avenue, New York 29, New York.

Twenty-Sixth Venereal Disease Postgraduate Conference, University of Tennessee College of Medicine, April 18-20. Dr. Henry Packer, Department of Preventive Medicine, University of Tennessee College of Medicine, Memphis 3, Tennessee.

University of Texas Postgraduate School of Medicine, Course in Rheumatic Diseases, Houston, Texas, February 27 through March 1. The University of Texas Postgraduate School of Medicine, Texas Medical Center, Houston 25, Texas.

International

Canadian Medical Association, Edmonton, Alberta, Canada, June 17-21. Dr. A. D. Kelly, 150 St. George Street, Toronto 5, Ontario, Canada.

College of General Practice, Montreal, Quebec, Canada, March 4-6. Dr. W. V. Johnston, 175 St. George Street, Toronto 5, Ontario, Canada.

Congress of International Anesthesia Research Society, Phoenix, Arizona, April 1-4. Dr. A. William Friend, Wade Park Manor, Cleveland 6, Ohio.

Congress of International Association for Study of the Bronchi, Lisbon, Portugal, May 25-26. Prof. F. Lopo de Varvalho, 138 rua de Junqueira, Lisbon, Portugal.

Congress of International Society for Cell Biology, St. Andrews, Fife, Scotland, August 28-September 3. Prof. H. G. Callan, Bell Pettigrew Museum, The University, St. Andrews, Fife, Scotland.

Congress of International Society of Orthopedic Surgery and Traumatology, Barcelona, Spain, September 16-21. International Society of Orthopedic Surgery and Traumatology, 34 rue Montoyer, Brussels, Belgium.

Congress of International Society of Surgery, Mexico City, Mexico, October 27-November 2. Dr. L. Dejardin, 141 rue Belliard, Brussels, Belgium.

Inter-American Congress of Pan American Medical Association, Mexico City, Mexico, November 18-22. Dr. Joseph J. Eller, 745 Fifth Avenue, New York 22, New York.

Interim Congress of Pan American Association of Ophthalmology, New York, April 7-10. Dr. Brittain F. Payne, 17 East 72nd Street, New York 21, New York.

International Conference on Audiology, St. Louis, Missouri, May 13-16. Dr. S. Richard Silverman, 818 South Kingshighway, St. Louis, Missouri.

International Congress of Clinical Pathology, Brussels, Belgium, July 15-20. Prof. M. Welsch, Universite de Liege, 32 Blvd. de la Constitution, Liege, Belgium.

International Congress of Dermatology, Stockholm, Sweden, July 31-August 6. Dr. C. H. Floden, Karolinska, Sjukhuset, Hudkliniken, Stockholm 60, Sweden.

International Congress of Electroencephalography and Clinical Neurophysiology, Brussels, Belgium, July 21-28. Dr. R. G. Bickford, Mayo Clinic, Rochester, Minnesota.

International Congress of International Society of Bronchoesophagology, Philadelphia, Pennsylvania, May 12-13. Dr. Chevalier L. Jackson, 3401 North Broad Street, Philadelphia.

MEETING AND ANNOUNCEMENTS

International Congress on Medicine and Surgery, Turin, Italy, June 1-9. Secretariat, Minerva Medica, Corso Bramante 83-85, Turin, Italy.

International Congress of Neurological Sciences, Brussels, Belgium, July 21-28. Dr. Pearce Bailey, National Institutes of Health, Bethesda 14, Maryland.

International Congress of Neurosurgery, Brussels, Belgium, July 21-28. Dr. William B. Scoville, 85 Jefferson Street, Hartford, Connecticut.

International Congress of Neuropathology, Brussels, Belgium, July 21-28. Dr. Ludo J. Bogaert, 47 rue de l'Harmonie, Antwerp, Belgium.

International Congress of Nutrition, Paris, France, July 24-29. Congress International de Nutrition, 71 Blvd. Pereire, Paris 17e, France.

International Congress of Otolaryngology, Washington, D. C., May 5-10. Dr. Paul H. Molinger, 700 North Michigan Avenue, Chicago 11, Illinois.

International Congress on Rheumatic Diseases, Toronto, Ontario, Canada, June 23-28. International Congress on Rheumatic Diseases, P.O. Box 237, Terminal "A," Toronto, Ontario.

International Gerontological Congress, Merano-Bolzano, Italy, July 14-19. Segreteria, Quarto Congresso Internazionale de Gerontologia, Viale Morgagni, 85, Firenze, Italy.

International League Against Epilepsy, Brussels, Belgium, July 21-28. Dr. Radermecker, Institut Bunge, 59 rue Philippe Milliot, Berchem, Antwerp, Belgium.

International Scientific Congress of International Congress of Surgeons, University, Mexico D.F., Mexico, Feb. 24-28. Secretary, Mexican Congress, International Congress of Surgeons, 1516 Lake Shore Drive, Chicago 10, Illinois.

International Symposium on Medical-Social Aspects of Senile Nervous Diseases, Venice, Italy, July 20-21. Secretariate, Viale Morgagni 85, Firenze, Italy.

International Voice Conference (Laryngeal Research Function and Therapy), Chicago, Illinois, May 20-22. Dr. Hans von Leden, 30 North Michigan Avenue, Chicago 2, Illinois.

Neuroradiologic Symposium, Brussels, Belgium, July 21-28. Professor Melot, Hôpital Universitaire St. Pierre, Brussels, Belgium.

Pan-Pacific Surgical Association, seventh congress, Honolulu, Hawaii, November 14-22, 1957. Write Dr. F. J. Pinkerton, director-general of the Pan-Pacific Surgical Association, Room 230, Young Building, Honolulu, Hawaii.

HARVEY TERCENTENARY CONGRESS

Since June, 1957, marks the tercentenary of the death of William Harvey, the discoverer of the circulation of the blood, the date will be commemorated by holding an International Congress on the Circulation, June 3 to 7, at the Royal College of Surgeons in London. The theme of the congress will be "A Review of the Present Knowledge of the Circulation," and the following subjects will be presented by world authorities in this field: Progress in knowledge of circulation from

the seventeenth century to the present time; the role of the heart in circulation; the results of cardiac surgery; coronary, pulmonary, fetal, cerebral, spanchic and peripheral circulation. Following the congress, a week-end conference on the more personal and biographical aspects of William Harvey's life will be held at his birthplace, Folkestone, Kent. Dr. F. A. Willius of the Mayo Clinic will be one of the participants in the congress. Further information may be obtained from the Congress Secretary, 11 Chandos Street, Cavendish Square, London W1, England.

MAYO CLINIC TO PRESENT CLINICAL REVIEWS

Once again the staff members of the Mayo Clinic and the Mayo Foundation will present a three-day program of lectures, discussions and demonstrations on problems of current interest in general medicine and surgery. There are no fees for this program which will be held on April 1, 2, and 3, 1957, and up to twenty-one hours of Category I credit may be obtained by the American Academy of General Practice members who attend. Attendance is limited, and those interested should communicate with Mr. R. C. Roesler, Mayo Clinic, Rochester, Minnesota.

FELLOWSHIPS FOR VACATION TIME STUDY FOR MEDICAL STUDENTS

The National Foundation for Infantile Paralysis has available a limited number of fellowships for medical students who wish to take advantage of vacation time for study during the calendar year, 1957. The program, administered by the Foundation through the deans of the medical schools, provides six fellowships for each approved medical school, two in each of the following categories: (1) research in the biologic and physical sciences related to medicine; (2) public health and preventive medicine; and (3) rehabilitation. Students must have completed one year toward the M.D. degree in order to be eligible for the research program. Application forms should be requested from the Dean of the Medical School where the student is enrolled. Further information may be obtained from Professional Education Division, National Foundation for Infantile Paralysis, 120 Broadway, New York 5, New York (after March 1, 301 East 42nd Street, New York 17).

STATE MEDICAL ASSOCIATION OFFICERS ANNOUNCED

Dr. J. Arnold Bargen, Rochester, took office as president of the Minnesota State Medical Association, January 1, succeeding Dr. R. H. Wilson, Winona. Dr. R. L. Page, St. Charles, is first vice president; Dr. W. E. Wellman, Rochester, second vice president, and Dr. B. B. Souster, St. Paul, was renamed secretary.

Dr. Donald McCarthy, Minneapolis, is treasurer, and Dr. H. M. Carryer, Rochester, speaker of the House of Delegates. Dr. C. L. Oppegard, Crookston, and R. R. Rosell, St. Paul, have been renamed chairman of the Council and executive secretary, respectively.

New members of the Council include Dr. W. B. Wells, Jackson, second district; Dr. C. G. Sheppard,

Hutchinson, fourth district; Dr. J. P. Medelman, St. Paul, fifth district. Dr. J. M. Stickney, Rochester, represents the first district; Dr. P. E. Hermanson, Hendricks, the third district; Dr. H. B. Sweetser, Minneapolis, the sixth district; Dr. W. W. Will, Bertha, the seventh district; Dr. C. L. Oppegard, Crookston, the eighth district, and Dr. Clarence Jacobson, Chisholm, the ninth district.

MEDICAL CONTINUATION COURSES AT UNIVERSITY OF MINNESOTA

The following medical continuation courses will be presented at the Center for Continuation Study, University of Minnesota, during the first quarter of 1957:

February 7-9—Cardiovascular Diseases for General Physicians

February 11-13—Anesthesiology for General Physicians

February 11-16—Neurology for General Physicians and specialists

March 4-6—Internal Medicine for Internists

March 18-20—Pediatrics for General Physicians

March 21-23—Obstetrics for Specialists

April 6—Trauma for General Physicians

April 8-10—Radiology for General Physicians

Details about these courses may be obtained from the Director, Department of Continuation Medical Education, 1342 Mayo Memorial, University of Minnesota, Minneapolis 14, Minnesota.

INTERNATIONAL PRIZES FOR FAMILY PHYSICIANS

A new series of prizes for family physicians of any country has been announced in London by Benger Laboratories, British pharmaceutical firm. The prizes which total 500 pounds in value will be known as the "Benger Prizes for Original Observations in General Practice." The ideas for which the pharmaceutical firm is looking may be concerned with the cause, diagnosis, treatment or prevention of any disease, and all entries will be published in a book available to physicians everywhere. The company believes "that among the obscure and unassuming family doctors of the world there may be another Jenner or another Lind." Entries may be in any form and of any length, and manuscripts or correspondence should be addressed to Benger Laboratories, Ltd., Holmes Chapel, Cheshire, England. All family physicians are eligible to participants.

TUMOR CONFERENCE

(Continued from Page 44)

surgery and the lymph nodes examined in the specimen were negative for metastases. The parotid gland substance itself also was negative for residual tumor.

The practice of thoroughly searching any pa-

tient with a lump in the neck or parotid region for a possible primary cancer in the pharynx, larynx, oral cavity, et cetera, is very worthwhile. Many times a lesion with the clinical appearance of a probable primary parotid tumor can be approached with the knowledge that it most likely represents a metastasis after the primary tumor in the head and neck region has been demonstrated and proved. Under these circumstances, it is possible to establish a somewhat more rational and beneficial course of therapy for the patient.

BLEEDING FROM THE GENITO-URINARY TRACT

(Continued from Page 20)

entire defect was roofed with organized hematoma. Microscopic examination of the kidney revealed large areas of necrosis and a renal infarct. The patient had a normal convalescence.

Summary

Hematuria should always be investigated promptly because of the high incidence of serious and yet curable conditions causing it. Many traumatic injuries to the kidney may be treated conservatively if they are observed carefully and good judgment is exercised. There is no routine therapeutic procedure applicable to all cases; each case must be carefully individualized. Evidence of severe renal damage out of proportion to the degree of trauma should arouse suspicion of a pre-existing renal disease. Six patients with serious injuries to various parts of the urinary tract are briefly described, all helped by timely surgical intervention. It is hoped that this review of bleeding from the genitourinary tract will serve as a reminder of the seriousness of the symptom.

Woman's Auxiliary

NATIONAL PRESIDENT TO SPEAK AT STATE BOARD MEETING

The mid-winter board meeting of the Woman's Auxiliary to the Minnesota State Medical Association will be held at 10:00 a.m. Wednesday, January 23, at the Minnesota Club in St. Paul. Registration for the meeting will be at 9:30.

Guest speaker is the national Auxiliary president, Mrs. Robert Flanders, Manchester, New Hampshire.

Mrs. Flanders first served on the board of directors of the Woman's Auxiliary to the American Medical Association as fourth vice president and chairman of the organization committee of the Eastern Region in 1948-1949. She was a director for two years, 1950-1952, and was chairman of the revisions committee in 1952-1953. She has served the Auxiliary on both the finance and executive committees. She was first vice president and chairman of the organization committee for two years, 1953-1955, and was the president-elect in 1955-1956.

In 1944-1946, she was president of the Woman's Auxiliary to the New Hampshire Medical Society and in 1930-1931 she served as president of the Woman's Auxiliary to the Hillsboro County Medical Society.

Mrs. Flanders' interests are many and varied. She has served as president of a number of organizations in her community including the Manchester Girls' Club, the Junior Associates of Elliott Hospital, Senior Associates of Elliott Hospital, and the Woman's Union of Franklin Street Church.

Her family consists of her husband, two daughters, two sons and four grandchildren. One of her sons is a physician in Indianapolis, Indiana.

NEWS FROM COUNTY AUXILIARIES

Hennepin

Mrs. L. P. Howell, Rochester, state president, was guest of honor at a Christmas luncheon meeting held at the Interlachen Country Club in Minneapolis, December 7.

Mrs. A. Cabot Wohlrabe, Minneapolis, sang a group of Christmas carols from a number of nations—Italy, Germany, France—including a Chinese lullaby. She was accompanied by Mrs. Russell Lindgren whose two young daughters, Ann and Mary, sang a group of Christmas songs. The youngsters were dressed as angels and carried lighted candles.

Approximately 135 members attended this Christmas program. A silver offering was taken for the Sarahurst Home for convalescing tuberculosis patients located in Minneapolis.

* * *

Mrs. Reuben Erickson presented the awards for the 1956 high school Tuberculosis Essay contest over radio station WCCO, Minneapolis, Saturday, December 8, and Saturday, December 15. She represented the Minnesota Auxiliary which co-sponsored the contest. Mrs. Wallace Ritchie, St. Paul, a member of the Ramsey County Auxiliary, assisted in the judging. The winners

in the senior high group were Mary Powelson, St. Cloud, Marlene Fischer, Pierz, and Kathleen Redpath, St. Paul. Karen Thorp, Duluth, and Carol Hudoba, New Brighton, won the junior high division.

* * *

A Hennepin Auxiliary committee headed by Mrs. Karl Anderson is developing a program for wives of medical students at the University of Minnesota. The committee is working with the Student AMA group at the University.

The Minneapolis District Dental Auxiliary entertained members of the Hennepin County Medical Auxiliary at a Christmas tea at the Prudential Life Insurance Building in Minneapolis, December 10. Mrs. Waldemar Johanson, St. Paul, member of the Ramsey County Medical Auxiliary, spoke on "Candles for Christmas." At the end of her talk, guests at the tea received candles which had been made by Mrs. Johanson.

Lyon-Lincoln

Lyon-Lincoln Auxiliary elected new officers in November: Mrs. John Myers, Canby, president; Mrs. Leonard Monson, Canby, secretary-treasurer. Mrs. M. I. Hauge, Clarkfield, was the speaker at the November meeting.

Red River Valley

Members of the Red River Valley Auxiliary held a joint dinner meeting with their husbands in Thief River Falls in November. After dinner, the Auxiliary members adjourned to the home of Dr. and Mrs. M. D. Starekow for their own meeting.

Zumbro Valley (Olmsted-Houston-Fillmore-Dodge)

The O-H-F-D group from now on will be known as the Zumbro Valley Medical Society Auxiliary. The group was host to the Region 1 Auxiliary meeting in Rochester early in November. A luncheon was held at the Rochester Golf and Country Club and the afternoon meeting was held at the Mayo Foundation House.

Mrs. C. L. Sheedy, Austin, chairman of the advisory committee, read some original verses about duties of a member of the advisory board. A number of other state officers gave résumés of their jobs. A discussion period followed.

Mrs. G. R. Diessner is president of the Zumbro Valley group and Mrs. Howard F. Polley is first district adviser.

However successful our treatment of tuberculosis in children and young adults may be, unless we control the disease in the higher age groups we shall be a long time reducing the incidence of the disease in the population. The active cases in elderly men and women are going to form the hard core of infection in the community that may give rise to local epidemics of acute cases among the young contacts. It behooves us, therefore, to discover, treat, and if necessary isolate these dangerous old men and women and to do all we can to protect our children and young adults from the risks to which they are exposed.—F. R. G. Heaf, M.D., J. Royal Inst. Pub. Health and Hygiene, November, 1955.

In Memoriam

CARL E. ANDERSON

Dr. Carl E. Anderson, who practiced medicine in Brainerd for a number of years, died October 22, 1956, in Moose Lake, Minnesota. He was sixty-three years old.

Born in South Dakota in 1893, Dr. Anderson received his medical education at the University of Minnesota. At one time he was chief of staff of St. Joseph's Hospital in Brainerd. He was a member of the Upper Mississippi Medical Society, the Minnesota State Medical Association and the American Medical Association. He had also practiced in Great Falls, Montana.

Survivors include his wife, Evelyn.

FREDERICK H. DUBBE

Dr. F. H. Dubbe, New Ulm, Minnesota, physician and surgeon, died November 30, 1956. He was sixty-one years old.

Born at Jordan, Minnesota, April 27, 1895, Dr. Dubbe graduated from Carleton College, Northfield, Minnesota, and received his medical education at the University of Minnesota. He interned at Minneapolis General Hospital, and at Northwestern Hospital, Minneapolis, and began practicing in New Ulm in 1920.

A member and past president of the Brown County Medical Society, Dr. Dubbe also belonged to the Southern Minnesota Medical Association, the Minnesota State Medical Association, the American Medical Association, and was a Fellow of the American College of Surgeons. He was also a member of the Brown County and Minnesota State Historical Societies, the Izaak Walton League, and the New Ulm Civic and Commerce Association. Dr. Dubbe was a charter member of the New Ulm Lions Club.

Survivors include his wife, Lillian, and two brothers, Emil and Carl, Jordan, Minnesota.

EDWIN G. KNIGHT

Dr. Edwin G. Knight, physician at Swanville, Minnesota, since 1943, died November 29, 1956, at Mounds Park Hospital, St. Paul. He was forty-two years old.

Dr. Knight was born in Randall, Minnesota, and graduated from St. Cloud Technical High School. He attended Macalester College, St. Paul, Jamestown College, Jamestown, North Dakota, and graduated from the University of Minnesota Medical School. Following his graduation, he practiced in Randall for a number of years.

From 1943 to 1951, he practiced with Dr. Edwin J. Simons in Swanville and had been alone since Dr. Simons moved to Minneapolis in 1951.

A member of the Upper Mississippi Medical Society, Dr. Knight also belonged to the Minnesota State Medical Association and the American Medical Association.

Survivors include his two children, Douglas, twelve, and Marcia, eleven; his stepmother, Mrs. S. G. Knight,

Swanville; one brother, Robert, Palo Alto, California; one sister, Mrs. Virgil Miller, Proctor, Minnesota. His wife preceded him in death less than a year ago.

MORRIS H. LAX

Dr. Morris H. Lax, St. Paul physician for more than thirty years, died in November, 1956. He was sixty-two years old.

Dr. Lax was born in Warsaw, Poland, in December, 1893. After emigrating to the United States, he attended St. Paul Mechanic Arts High School and the University of Minnesota, where he received his degree in medicine in 1922. He interned at Minneapolis General Hospital and opened a private practice in St. Paul. His field of special interest was proctology.

A member of the Ramsey County Medical Society, Dr. Lax also belonged to the Minnesota State Medical Association and the American Medical Association.

Survivors include his wife, Marian, St. Paul.

GEORGE H. MESKER

Dr. George H. Mesker, pioneer physician of Olivia, Minnesota, died November 19, 1956. He was eighty-three years old.

Dr. Mesker was born in Sibley County, July 10, 1873. He attended high school at Henderson and graduated from the University of Minnesota medical school. After practicing for one year at Chokio, he moved to Olivia in 1897.

During World War II, he served with the U. S. Army medical corps in Savage, Minnesota, Pueblo, Colorado, and St. Louis, Missouri. In 1945, he returned to Minnesota and served for four years as a member of the staff of Cambridge State Hospital. In 1949, he moved back to Olivia.

Dr. Mesker served as a member of the board of education in Olivia for thirty-three years and was president for several terms. He was also village mayor and had served on the village council.

As first president of the Renville-Redwood County Medical Society, Dr. Mesker also belonged to the Minnesota State Medical Association which counted him among its "50 Club" members. He was also a member of the American Medical Association and a board member and past president of Riverside Sanatorium Committee.

Survivors include his wife, Florence; one son, Clifford, St. Louis, Missouri; one daughter, Mrs. James Baker (Florence), Munster, Indiana; six grandchildren, and one sister, Mrs. Lizzie Lindenberg, Sunnyside, Washington.

DAVID E. NELSON

Dr. David E. Nelson, Alexandria physician and surgeon for many years, died November 11, 1956. He was seventy-four years old.

IN MEMORIAM

Dr. Nelson was born in Anoka, Minnesota, August 17, 1882. He attended the Anoka and St. James, Minnesota, schools, Valparaiso University, Valparaiso, Indiana, and received his medical education at the Chicago College of Medicine and Surgery. He interned at Cook County Hospital, Chicago, and served in the U. S. Army Medical Corps during World War I.

Dr. Nelson had also practiced medicine in Chicago, Brainerd and Minneapolis.

He served as health officer for the city of Alexandria at one time and had been a member of the Park Region District and County Medical Society, the Minnesota State Medical Association, and the American Medical Association.

GEORGE H. NORRIS

Dr. George H. Norris, physician in Annandale, Minnesota, for fifty-two years, died November 29, 1956. He was eighty-six years old.

Dr. Norris was born in Hamilton, Canada, and received his medical education at the University of Michigan. He practiced in Clearwater, Minnesota, for two years before moving to Annandale in 1904.

A member of the Masonic Lodge of Annandale, Dr. Norris was also the first commander of the Annandale American Legion Post. He served as a major in the U. S. Army Medical Corps during World War I.

At one time, he was a member of the Wright County Medical Society and the Minnesota State Medical Association.

He is survived by one daughter, Mrs. Frances Heindinger, Tulsa, Oklahoma, and three sons, George S., Houston, Texas; Robert B., Minneapolis, and Dr. Neil T., Caledonia, Minnesota.

CHARLES SIMON RAADQUIST

Dr. Charles S. Raadquist, Hibbing physician for nearly forty years, died November 9, 1956. He was seventy-two years old.

Dr. Raadquist was born at Warren, Minnesota, November 21, 1883. He graduated from the University of Minnesota medical school in 1915 and took post-graduate work at Ancker Hospital, St. Paul, and Post-graduate Hospital, Chicago.

A member of the staff of the Adams Clinic in Hibbing, Dr. Raadquist was also a member of the Range Medical Society, the St. Louis County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Dr. Raadquist was chief of staff at Hibbing General Hospital and at one time was health officer for the Village of Hibbing. He was a member of Wesley Methodist church, the Rotary and Kiwanis Clubs, Mesaba Lodge No. 225, A.F.&A.M., Iron Range Lodge of Perfection, and a member of the American Legion as a veteran of World War I.

Survivors include his wife, Pauline; a brother, Carol W. Raadquist, Minneapolis, and a nephew, Clinton Raadquist, also of Minneapolis.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

TWO SENTENCED AT LE CENTER FOR ABORTION

Re: State of Minnesota vs. James Jerome Meyers and LaDess Weinand

On November 30, 1956, James Jerome Meyers, twenty-four, a radio technician at Le Center, and LaDess Weinand, eighteen, 3862 Orchard Avenue North, Robbinsdale, appeared before the Hon. Harold Flynn, Judge of the District Court at Le Center, and were sentenced for the crime of abortion. The defendant Meyers was sentenced to serve a term of not to exceed four years in the State Reformatory for Men at St. Cloud. Miss Weinand was sentenced to the custody of the Youth Conservation Commission for a period of not to exceed four years, but Judge Flynn suspended the sentence and placed her on probation for a period of two years. Both defendants had previously entered a plea of guilty to the abortion charge before Judge Flynn on October 29, 1956, at which time a pre-sentence investigation was ordered by the court.

The defendant Meyers admitted in a signed statement which he gave to the authorities that he was responsible for the pregnancy of Miss Weinand. He further stated that, after unsuccessful attempts to have her aborted by other means, he advised the defendant Weinand to jump from the top of a refrigerator in his home. Miss Weinand followed his advice and the following day, September 28, 1956, she aborted.

While being questioned by Judge Flynn prior to being sentenced, Meyers admitted that he had been convicted of car theft in Aberdeen, South Dakota, on November 15, 1949, at which time he was given a suspended sentence of two years and placed on probation for the same period of time. He also admitted a conviction for using an automobile without the owner's permission on April 13, 1950, and that he was sentenced to serve a term of not to exceed five years in the State Reformatory for Men at St. Cloud, Minnesota. The defendant was released from the reformatory on April 10, 1952. In addition Meyers stated to Judge Flynn that he had been convicted of auto theft again in May, 1952, at Winona, Minnesota, being sentenced at that time to serve a sentence of from one to twenty years, also at the State Reformatory for Men. Meyers served slightly over two years of his sentence until June 23, 1954, when he was allowed to leave the reformatory on parole.

PRIOR LAKE WOMAN SENTENCED FOR OBTAINING NARCOTICS BY MEANS OF FORGED PRESCRIPTION

Re: State of Minnesota vs. Mildred Martha Mueller

On November 29, 1956, Mrs. Mildred Martha Mueller, forty, Route #2, Prior Lake, was sentenced by the Hon. Theodore B. Knudson, Judge of the District Court of Hennepin County, to a term of not to exceed five years at the State Reformatory for Women, Shakopee, for the crime of obtaining narcotics by the forgery of a prescription. Previously, on October 16, 1956, the defendant had entered a plea of guilty before Judge Knudson to an information charging her with that offense. However, Judge Knudson suspended the sentence and placed Mrs. Mueller on probation for a period of two years, one of the conditions of her probation being that she consult a doctor of medicine once each month and also authorize a report in reference to her physical condition to be sent by that doctor to the Hennepin County Probation Office.

The defendant, who has no prior criminal record, had been obtaining prescriptions for morphine sulphate from a Minnesota physician but when he refused to write further prescriptions for her, she forged the physician's name to prescriptions for morphine sulphate, which were written by her on plain white slips of paper. After a number of these prescriptions had been presented in August, 1956, at a Minneapolis drug store and narcotics obtained thereon by Mrs. Mueller, the pharmacist became suspicious and notified the authorities. A representative of the Minnesota State Board of Medical Examiners then contacted the physician whose signature had been forged and the physician, after inspecting the various prescriptions, gave a signed statement at the Minneapolis Police Department in which he said that the signatures on the various prescriptions were not his. A criminal complaint, which was signed by the Medical Board's representative, was then issued by the Hennepin County Attorney's Office and Mrs. Mueller was apprehended and placed in jail. However, Mrs. Mueller became ill and was hospitalized at Minneapolis General Hospital until October 8, 1956.

TWO MINNEAPOLIS MEN SENTENCED FOR ABORTION

Re: State of Minnesota vs. Walter John Rapacz and Harland K. Springer

On October 26, 1956, Harland K. Springer, thirty-four, 6321 Clinton Avenue, Richfield, was sentenced by the Hon. Levi M. Hall, Judge of the District Court of Hennepin County, to a term of not to exceed four years in the Minnesota State Prison at Stillwater, pursuant to his plea of guilty, which Springer had previously entered on August 29, 1956, to an information charging him with the crime of abortion. However, Judge Hall stayed the execution of the sentence for a period of five years and placed the defendant on probation during this time.

The defendant Rapacz, thirty-two, 4327 Cedar Avenue, Minneapolis, who was charged with the same offense, entered a plea of not guilty before Judge Irving R. Brand of Hennepin County District Court on August 1, 1956, and the case was set for trial. On September 28, 1956, the trial of Rapacz by jury commenced before Judge Brand. The defendant took the witness stand in his own behalf during the course of the trial and asserted as an alibi that on July 11, 1956, the day that the abortion took place, he was working at his job at an automobile company on Lake Street in Minneapolis and therefore could have taken no part in the crime. It was not the claim of the prosecution that Rapacz performed the abortion but that he had transported the patient, a thirty-four-year-old Minneapolis divorcee with three children, to the place where the illegal operation was performed and also that the money paid for the abortion was paid to him. The person who was charged with actually performing the abortion was found not guilty by a jury in a separate trial. The evidence at the Rapacz trial disclosed that the sum of \$250 was paid for the abortion, of which the defendant Springer paid \$230 and the woman who submitted to the abortion paid the remainder. The case came to the attention of the authorities when the patient became ill and was hospitalized in a Minneapolis hospital.

The defendant Rapacz at the conclusion of the trial was found guilty by the jury, and Judge Brand at that time referred the case to the Hennepin County Probation Office for a pre-sentence investigation. On November 15, 1956, Rapacz appeared before Judge Brand for sentencing, but upon being questioned about the crime Rapacz still denied his guilt so Judge Brand directed that the defendant should be given a lie detector test. However, later on that same date, Rapacz had a change of heart

and again appeared before Judge Brand and admitted that he had a part in the abortion, whereupon he was sentenced to a term of seven years at the State Prison at Stillwater. However, Judge Brand stayed the execution of the sentence and placed the defendant on probation for a period of five years.

Rapacz has three prior convictions as follows: On May 5, 1942, he was convicted in the United States District Court in Minneapolis of stealing and forging United States postal money orders, at which time he was placed on probation until June 3, 1945. On February 10, 1943, the Hon. Paul N. Guilford, Judge of the District Court of Hennepin County, sentenced Rapacz to a term of not to exceed eighteen months in the State Reformatory for Men at St. Cloud, upon his conviction of the offense of burglary in the third degree. The defendant was released from that institution on May 10, 1944, to the custody of the United States Marshal for a violation of his probation. On July 26, 1946, Rapacz was convicted in the District Court of Hennepin County of the offense of forgery in the second degree, whereupon Judge Levi M. Hall sentenced him to serve two and one-half years in the Minnesota State Prison at Stillwater.

General Interest

Dr. and Mrs. A. E. Brown of Oronoco returned November 3 from a two-month tour of hospitals and clinics in Europe. Dr. Brown is a staff member of the Mayo Clinic.

* * *

The American Medical Women's Association has named **Dr. Helen Knudsen**, chief of hospital services for the Minnesota Department of Health, as "Medical Woman of the Year." Under her direction, more than \$16 million of federal aid has been spent in Minnesota's Hill-Burton hospital program, and more than fifty-five hospitals and public health centers have received aid from this fund.

* * *

Dr. John Coe, Minneapolis General Hospital and president of the Minnesota Society of Clinical Pathologists, was an honored guest at the November 13 meeting of the Minnesota Society of Medical Technologists at the University of Minnesota Center for Continuation Study. The latter organization also held a continuation course in clinical chemistry for technologists, at which **Drs. Paul Hagen**, Minneapolis Veterans Hospital, **James Melby** and **Frederick Goetz**, University of Minnesota hospitals, served on the faculty.

* * *

Dr. John S. Siegel of Virginia, and **Dr. E. R. Addy** of Gilbert attended a one-week course in modern therapeutics in Chicago, at which lecturers came from the University of Chicago, Northwestern University Medical School, University of Minnesota, and Duke University.

* * *

Dr. Louis A. Buie, Rochester, received mention in the December 11, 1956 issue of *Look* magazine in an article devoted to the proposed revised principles of medical ethics. Dr. Buie is chairman of the AMA Council on Constitution and By-laws, which was given the task of revising the Principles.

* * *

The second annual Golden Deeds Award of the Rochester Exchange Club was presented on November 27 to **Dr. Arthur H. Sanford** of Rochester. Dr. Sanford's years of unselfish service on the School Board, Library Board, Olmsted County Historical Society and in the Boy Scouts, as well as many personal "golden deeds" to friends and neighbors, formed the basis for his selection. Dr. Sanford, who is now director of laboratories at Rochester State Hospital, was retired from the Mayo Clinic as head of the section of clinical pathology in 1949, and is an emeritus member of the Clinic staff.

* * *

The Air Force Exceptional Service award was presented to **Dr. Donald A. Hastings** of the University of Minnesota Medical School, by Secretary of the Air Force **Donald A. Quarles**. This is one of four awards

given to scientists throughout the nation, and was given to Dr. Hastings for meritorious service to the Air Force from 1950 through 1955. Dr. Hastings has served as chairman of the aeromedical panel of the scientific advisory board to the Air Force chief of staff.

* * *

Dr. J. B. Erich of the Mayo Clinic, Rochester, was one of the speakers at a meeting of the American Fracture Association in Chicago in late November.

* * *

At the meeting of American Academy of Cerebral Palsy held in Chicago in November, the Mayo Clinic was represented by **Drs. D. J. Erickson**, **L. E. Harris**, **E. W. Johnson**, **R. G. Dickert** and **C. R. Sullivan**.

* * *

The newly-elected president of the voting staff of the Mayo Clinic is **Dr. H. J. Moersch**, chairman of the sections of internal medicine, and professor of Medicine in the Mayo Foundation. Other new officers for 1957 are **Drs. L. M. Eaton**, vice president; **C. A. Owen, Jr.**, secretary; and **O. S. Culp** and **R. L. Parker**, councilors. **Drs. H. B. Burchell** and **C. A. Good** will replace **Drs. S. F. Haines** and **T. B. Magath** on the board of governors of the Clinic. **Dr. J. A. Borgen**, retiring president of the staff, and **Dr. Victor Johnson**, director of the Mayo Foundation, both addressed the group. Two retiring members, **Dr. L. T. Austin**, senior consultant and formerly head of the section of dentistry, and **Dr. A. C. Davis**, consultant in medicine, both received scrolls.

* * *

Dr. A. D. Fetzek, physician and surgeon, has begun the practice of medicine in Austin, having completed his service with the Air Force.

* * *

Dr. C. Gordon Vaughn, who is limiting his practice to dermatology, opened new offices at 1065 Lowry Medical Arts Building, St. Paul, on December 1.

* * *

A Minnesota-born physician, **Dr. Edward M. Gans**, formerly of Eveleth, was honored by the American Medical Association by being named the nation's outstanding family doctor of the year. A graduate of the University of Minnesota, Dr. Gans now resides in Harlowton, Montana, where he serves the range country in central Montana.

* * *

Dr. H. Z. Giffin has the honor of being the first member to have reached the fiftieth anniversary of his joining the Mayo Clinic staff. He became affiliated with the Clinic in 1906 and became an emeritus staff member in 1946.

* * *

At the National Conference of Editorial Writers, held in Minneapolis, November 14 through 17, **Dr. Charles W. Mayo** of Rochester, United States delegate to the United Nations, was the banquet speaker. He stressed

the fact that if medical research is to advance, those engaged in the various research fields must have ready access to the clinician, the surgeon, and the patient, and that the areas of medical research and the actual practice of medicine are no longer separate spheres of interest.

* * *

On Thursday, November 8, **Dr. L. O. Underdahl** of the Mayo Clinic addressed the annual meeting of the Minnesota Dietetic Association on the subject of "The Use of Oral Hypoglycemic Agents in the Treatment of Diabetics."

* * *

Dr. H. Waltman Walters, surgeon at the Mayo Clinic and rear admiral in the medical corps, U. S. Naval Reserve, was the convocation speaker at Shattuck School, Faribault, Tuesday, November 13. He addressed the students on the subject of "Medicine as a Career."

* * *

Drs. George Baker and **Alfred Uihlein**, both of the section on Neurological Surgery of the Mayo Clinic, presented papers at the eighteenth annual meeting of the American Academy of Neurological Surgery in Phoenix, Arizona, November 7 to 11. Dr. Baker discussed plastic neurosurgical procedures on the scalp and skull, and Dr. Uihlein outlined fractional and pneumoencephalography. Dr. Baker was elected vice president of the organization.

* * *

Dr. and Mrs. Coolidge S. Wakai are at home in Rochester following their marriage in Los Angeles, October 27. Dr. Wakai is a fellow at the Mayo Foundation, and his bride, the former **Edith S. Yamasaki** of Los Angeles, was a social worker prior to her marriage.

* * *

Dr. Benedik Melby, octogenarian and beloved family physician of Blooming Prairie, accompanied by his wife, spent three weeks traveling in the East, visiting New York, Washington, and Detroit, during the early fall.

* * *

The community of Frost paid tribute on November 18 to **Dr. Lewis E. Hanson** on the twenty-fifth anniversary of his serving that community as a physician. Dr. Hanson has been active in civic and religious affairs in his area of practice which also includes Bricelyn, Minnesota, and Rake, Iowa.

* * *

To point up Diabetes Detection Week, the *Minneapolis Star* carried a two-column feature story of the work **Dr. Arnold Lazarow**, head of the Anatomy Department of the University of Minnesota, is doing with ten rhesus monkeys who have had diabetes for three years. Also reported was the experimental removal of the pituitary gland in two middle-aged men threatened with blindness as a complication of diabetes, in both of whom insulin requirements have now dropped sharply.

* * *

Partners in the new Koronis Medical Center at Paynesville are **Drs. Thomas E. Vanderpool** and **Kermit J. Halverson**, both graduates of the University of Minnesota School of Medicine.

The North Central Medical Conference in its annual meeting in St. Paul named **Dr. R. G. Mayer**, Aberdeen, South Dakota, as president-elect. This organization is composed of physicians from Iowa, Minnesota, Nebraska, Wisconsin, North and South Dakota.

* * *

East Range Clinics at Aurora has recently established its fifth affiliated branch at Hoyt Lakes, with **Dr. Raymond J. Chittum** in charge. Other East Range Clinics are located in Virginia, Eveleth, Biwabik and Aurora.

* * *

Dr. Morris H. Lax, St. Paul physician and staff member of Bethesda Hospital, died of a heart ailment on November 21.

* * *

Aurora, Minnesota, turned out en masse on December 2 to pay tribute to **Dr. Ivor T. Dahlin**, beloved general practitioner and for years the lone physician in the Aurora area, on the occasion of his retirement from the active practice of medicine.

* * *

Dr. John N. Olinger, a specialist in obstetrics and gynecology, is now associated with **Dr. Louis A. Loes** in a new clinic in St. Cloud. Dr. Olinger, who is a junior member of the American College of Surgeons, graduated from the Northwestern University Medical School and served for two years in the U. S. Air Force.

* * *

The East Range Clinics have added to their staffs, **Dr. Leon K. McGill**, an obstetrician and gynecologist. While Dr. McGill will be primarily attached to the clinic in Virginia, he will also serve the branches of the clinic at Eveleth and Aurora.

* * *

The North Central Medical Conference at its annual meeting in St. Paul in mid-November, awarded **Dr. William F. Braasch**, emeritus member of the Mayo Clinic staff, a citation for his contributions to the welfare of medicine.

* * *

Newly elected officers of the Ramsey County Medical Society are **Drs. J. Allen Wilson**, president; **Francis W. Lynch**, president-elect; and **Edward C. Gibbs**, secretary-treasurer. **Dr. A. E. Ritt** is the outgoing president.

* * *

Dr. Joseph B. Gaida, St. Cloud, was inducted a Fellow of the International College of Surgeons (Eye) in Chicago, last September.

* * *

"Plastic and Reconstructive Surgery Using Skin Grafts and Flaps" was the subject presented by **Dr. Merrill D. Chesler**, Minneapolis, at the November 26, 1956 meeting of the Blue Earth County Medical Society at the Mankato Clinic.

* * *

Dr. John J. Regan, Minneapolis, has been appointed attending psychiatrist at the Hamm Memorial Psychiatric Clinic. A graduate of St. Thomas College and the University of Minnesota Medical School, Dr. Regan served as a naval medical officer during World War II.

Reduced Hypermotility with Pro-Banthine® Improves Visualization

*Posterior-anterior film: definite hyperperistalsis with poor duodenal visualization.**

Posterior-anterior film after 15 mg. of Pro-Banthine intramuscularly: chronic duodenal ulceration clearly disclosed.

The same anticholinergic action which has made Pro-Banthine (brand of propantheline bromide) the outstanding therapeutic agent in peptic ulcer has also proved valuable in diagnosis.

By controlling the hypermotility, Pro-Banthine may permit delineation of a lesion otherwise not clearly visualized.

The technic is simple: If the first set of films shows hypermotility but no filling defect is demonstrable, reexamination is

done a few minutes after intramuscular injection of 15 mg. or a half hour after oral administration of 30 mg. of Pro-Banthine.

This procedure has the additional advantage of demonstrating the patient's response to a given dosage of the drug.

G. D. Searle & Co., Chicago 80, Illinois, Research in the Service of Medicine.

After completing his fellowship in psychiatry at the University of Minnesota, he served for a time as a staff member of the Minneapolis Veterans Administration Hospital. He has just returned from Hawaii where he was a supervising psychiatrist in the Territorial Hospital. Dr. Regan is a member of the American Psychiatric Association, a diplomate of the American Board of Psychiatry and Neurology, and is a clinical instructor at the University of Minnesota Medical School.

* * *

Dr. Joe R. Brown of the Mayo Clinic presented a paper at a meeting of the American Speech and Hearing Society in Chicago in late November, and represented the field of neurology at the annual workshop of the Conference of Rehabilitation Centers in Washington, D. C.

* * *

At the Seattle interim meeting of the American College of Chest Physicians, Dr. H. J. Moersch of Rochester presided and also acted as moderator of a chest disease conference, and Dr. A. M. Olsen, also of Rochester, presented a paper.

* * *

A number of staff members of the Mayo Clinic attended and participated in the interim session of the American Medical Association in Seattle, Washington, November 27-30, 1956. Drs. E. V. Allen, J. A. Borgen, R. R. Kierland, and F. H. Krusen were delegates, and Dr. Allen participated in a panel discussion. Other Clinic physicians taking part in the program were Drs. D. C. Dahlin, W. S. Fowler, C. H. Hodgson, W. F. Kvale, and A. M. Olsen. Others attending were Drs. G. R. Diessner, N. O. Hanson, and W. E. Wellman.

* * *

The Minnesota Heart Association conducted an orientation program for members of the Ramsey County Medical Society at Ancker Hospital, St. Paul, December 6. The program was arranged by Dr. John F. Briggs, chairman of the Minnesota Heart Association's professional education committee. Dr. William F. Mazzitello, director of postgraduate medical education at Ancker Hospital, conducted a tour of the research facilities and animal laboratories where studies of heart ailments are being conducted. Dr. Milton M. Hurwitz, St. Paul, vice president of the association, presided at a dinner meeting following the tour.

* * *

Dr. R. W. Koucky, Minneapolis, spoke at the second annual meeting of the Minnesota State Association of Blood Banks at the University of Minnesota, November 15, 1956.

* * *

The Steele County Medical Society, the Steele County Nursing Service and the Owatonna City Hospital are co-sponsoring a class for prospective parents at the Owatonna City Hospital.

* * *

Dr. L. W. Morsman, Hibbing, was honored by members and the auxiliary of the Range Medical Association at their annual meeting in Virginia recently. Dr.

Morsman has practiced medicine for fifty years. Judge James L. Underhill, Virginia, the main speaker at this meeting, discussed relations between the medical and legal professions.

* * *

Dr. George E. Thomas, Minneapolis, was honored at a luncheon recently on the occasion of his retirement from practice after fifty-one years. Dr. Thomas has had his office at the corner of Lake Street and Nicollet Avenue since 1905. A complete feature story on the doctor appeared in the November 29, 1956, issue of the *East Minneapolis Argus*.

* * *

Dr. Roger Johnson, Excelsior, Minnesota, was named chief of staff of the Waconia hospital at the annual meeting of the hospital in November. Dr. John Clarke, Watertown, was named vice-chief of staff and Dr. Charles Bean, Waconia, was named secretary-treasurer.

* * *

Dr. Vernon D. E. Smith, St. Paul, showed hunting and skiing movies at a sports program sponsored by the St. Paul Smith College Club in December.

* * *

Dr. Edgar V. Allen, Rochester, newly named president of the American Heart Association will open the Heart Fund drive in the Twin Cities in February. This appearance will be one of his 125 official visits during his year in office.

* * *

Dr. Charles L. Steinberg, St. Paul pediatrician, spoke on "Your Child Today" at a meeting of the Child Psychology Study Circle in St. Paul recently.

* * *

Dr. Nathan K. Jensen, Minneapolis, was featured in the December 7, 1956, edition of the *Minneapolis Star*. Dr. Jensen saved his son, Niels, and Phillip Contrain, a French exchange student living with the Jensens, from drowning on Medicine Lake early in December. The three were sailing in an iceboat on the lake when they hit a patch of open water and fell into the lake in water twenty feet deep.

* * *

New officers of the Association of Fellows of the Mayo Foundation were elected at the annual meeting of the group in Rochester in November.

Dr. William Spencer Payne is president; Drs. John U. Gardner, vice president; Dr. Donald F. Phillips, secretary; Dr. John W. Vance, treasurer, Dr. D. L. Tuffanelli, athletic chairman, and Dr. Robert J. Spencer, social chairman.

* * *

Drs. William H. Hengstler and Frank Babb, St. Paul, took part in a panel discussion on medical-legal problems at a joint meeting of the Ramsey County Medical Society and the Ramsey County Bar Association in November. St. Paul attorneys Charles Murnane and Richard Kyle were also on the panel. Warren E. Burger, judge of the United States circuit court of appeals, was moderator.

versity of Minnesota, has been appointed professor of surgery and head of the section of orthopedic surgery at the University of Kansas medical school. Dr. Peltier assumed his new position January 1.

* * *

Dr. Stuart W. Arhelger, Minneapolis, was guest speaker at the third annual cancer symposium of the Montgomery Society for Cancer Control, Dayton, Ohio, in October. His subject was "Advances in the Diagnosis and Operative Management of Gastric Cancer."

* * *

Dr. John R. Earl, St. Paul, has been elected chairman of the Minnesota Council of Churches board of trustees. The first layman elected to this office, Dr. Earl succeeds the late Rt. Rev. Stephen E. Keeler, Episcopal bishop of Minnesota.

* * *

Dr. Morris L. Cable, Minneapolis, was the victim of a robbery early in November. Some \$300 worth of narcotics in a medical bag was stolen from his car.

* * *

Dr. Paul J. Bilka, Minneapolis, spoke at the November meeting of the Red River Valley Medical Society in Thief River Falls, on the diagnosis of various types of arthritis and new methods of treatment. After a joint dinner session with the doctors, the Red River Valley Auxiliary attended a meeting at the home of Dr. and Mrs. M. D. Starekow.

* * *

Dr. James Taggart Priestley was elected chairman of the Board of Governors of the Mayo Clinic at the annual business meeting of the board, Wednesday, December 19. Dr. Priestley, who has been a member of the board since 1947 and vice chairman since 1953, succeeds Dr. Samuel F. Haines, chairman since 1953, who will retire from the Mayo Clinic in 1957. Dr. Priestley is head of the section of surgery in the Mayo Clinic and professor of surgery in the Mayo Foundation Graduate School, University of Minnesota.

Dr. Hugh R. Butt, specialist in internal medicine, was elected vice chairman of the board, and Mr. J. W. Harwick was re-elected secretary. Two new members of the board also assumed office at the annual business meeting—Dr. Howard B. Burchell, a specialist in internal medicine, and Dr. C. A. Good, specialist in roentgenology.

* * *

Dr. R. H. Wilson, Winona, and Dr. R. L. Page, St. Charles, were featured in a special article in the December 22, 1956, edition of the *Winona Daily News*, as presidents of two of Minnesota's leading medical organizations. Dr. Wilson was 1956 president of the Minnesota State Medical Association and Dr. Page is immediate past president of the Minnesota Academy of General Practice; he is now vice president of the State Medical Association.

* * *

Dr. John Schindler, Monroe, Wisconsin, author of the best-seller "How To Live 365 Days a Year," spoke at the University of Minnesota farm campus during the annual "Farm and Home Week" in January. His appearance was sponsored by the Minnesota State Medical Association.

INCREMIN*

LYSINE-VITAMIN SUPPLEMENT **LEDERLE**

CLINICAL REVIEWS MAYO CLINIC and MAYO FOUNDATION

ROCHESTER, MINNESOTA

April 1, 2, and 3, 1957

Staff members of the Mayo Clinic and the Mayo Foundation for Medical Education and Research will present again this year a three-day program of lectures, discussions and demonstrations on problems of current interest in general medicine and surgery.

Up to twenty-one hours of Category I credit may be obtained by American Academy of General Practice members who attend.

There are no fees for this program.

The number of physicians who can be accommodated is necessarily limited. Those wishing to attend should communicate with Mr. R. C. Roesler, Mayo Clinic, Rochester, Minnesota.

THE TRUTH ABOUT CANCER. By Charles S. Cameron, M.D. 268 pages. Price, \$4.95. Ridgewood, New Jersey: Prentice Hall, 1956.

The author's purpose in writing this book was to inform his readers, the general public, about the fight against cancer and to emphasize each individual's responsibility for his or her own life and health. It is a remarkably lucid portrayal of the purposes and accomplishments of the first decade of the American Cancer Society's activities, during which time the author served as its capable and irrepressible medical and scientific director. An attitude of optimism pervades the narrative, and the style is simple and very readable. As evidence of this, the reviewer's high school daughter picked up the book at home, read it through and proceeded to write a review of it for her English class.

Dr. Cameron is generally recognized by all who have heard him speak and have worked with him as an unusual combination of medical scientist, scholar, and organizational director of exceptional ability. This fall he resigned his position with the American Cancer Society to become the Dean at Hahnemann Medical College.

"The Truth About Cancer" merits a place of prominence in every public and school library. It should be read as widely as possible, by the general public as well as by the medical profession. In his preface to the book, AMA President Elmer Hess concludes with this comment: "I can imagine no book calculated to

yield more important dividends in life and health than this one."

PHILIP F. ECKMAN, M.D.

THE DOCTORS: A GREAT BEHIND-THE-SCENES NOVEL OF THE PARISIAN MEDICAL WORLD. By André Soubiran. Translated from the French by Oliver Coburn. 360 pages. Paper, 50 cents. New York: Popular Library, 1956.

This novel describes "the lives and loves of Parisian medical students." However, it is difficult to learn much of the training of a Parisian doctor.

The novel is involved with the patients on the wards, students on the wards, interns on the wards, and the parties outside of the wards.

The hero is Jean Nerac, a vague figure.

It can be enjoyed as a light novel, but with no serious message of description of Parisian students.

The novel has recently been made into a movie.

C.J.C.

* * *

The knowledge obtained from tuberculin tests is of value to the community and to the health department in comparing the local rate of infection with that in other areas of the country. Uniform testing of school children is valuable to the health department in focalizing the problem in certain sections of the community, in certain racial groups, and in special geographic regions. While it is desirable to test persons of all ages, this presents certain difficulties and the uniform testing of school children with a uniform dosage of tuberculin appears to provide a satisfactory means of comparing tuberculin sensitivity in various areas.—MICHAEL L. FURCOLOW, M.D., *Am. J. Pub. Health*, September, 1956.

Annual Clinical Conference

CHICAGO MEDICAL SOCIETY

March 5, 6, 7 and 8, 1957

Palmer House • Chicago

Daily Half-Hour Lectures by Outstanding Teachers and Speakers on subjects of interest to both general practitioner and specialist

Panels on Timely Topics

Daily Teaching Demonstrations

Medical Color Telecasts

Scientific Exhibits worthy of real study and helpful and time-saving Technical Exhibits

The Chicago Medical Society Annual Clinical Conference should be a **MUST** on the calendar of every physician. Plan now to attend and make your reservation at the Palmer House.

Original Contributions

Psychosomatic Aspects of Heart Disease

RICHARD M. MAGRAW, M.D.
Minneapolis, Minnesota

THE PSYCHOSOMATIC aspects of heart disease are presented from three standpoints. First, they are discussed with regard to that heterogeneous group of symptoms or illnesses ordinarily lumped together under the term cardiac neurosis or "functional" heart disease. These are symptoms of varying degrees of complexity ranging from pain in the chest and shoulder and complaints of shortness of breath to feelings of fatigue and weakness which, for one reason or another, are considered by the patient to be a result of a disorder of his heart and circulatory system, although they are clearly a function of his mental and emotional state. Second, a few of the common emotional reactions of organic heart disease are presented, using as illustrations some of those reactions which, in my judgment, have not received the attention they merit. Third, I shall make some recommendations for managing psychomatic problems associated with the heart, recommendations which are broadly applicable to what has been called the psychological half of medicine.

"Functional" Heart Disease or Cardiac Neurosis

It is important to bear in mind that cardiac neurosis is not a specific diagnostic term and that many different conditions and disorders are lumped together in this category. In clinical usage this term may be applied either when a patient has a strong suspicion or conviction that he has heart disease when he has not (usually called "functional" heart disease), or when he complains excessively or is excessively disabled with a diseased heart. In some of these latter cases the presence of a cardiac lesion, usually, but not necessarily, of minor consequence, appears to focus the patient's awareness on this organ, and complaints about the heart may become the chief vehicle for

the expression of the anxiety, anger, and/or guilt of the patient's life experiences.

In regard to the patient with so called "functional" cardiac symptoms, such a label is not a specific diagnosis, and consequently our understanding of such cases will depend on how far we can go beyond this point to get into the actual mechanisms by which the symptoms come about in a given case. There are many possible mechanisms which may be involved, but, contrary to what the name implies, the symptoms we commonly label "functional" usually are not produced primarily by any physiologic process or change, such as changes in blood pressure or pulse rate.* Rather, these symptoms are usually produced by the psychologic mechanism of symbolism wherein the patient reads into his body a mental picture or image of pathology, as if it were really present. To some degree all symptoms which a patient reports are colored by his mental picture of what is going on within him, so that a measure of individuality referred to as "subjectivity" is introduced in most descriptions of symptoms. However, there are many symptoms in which, for all practical purposes, the whole of the symptom is nothing more or less than an emotionally-charge symbol or mental image projected onto the body, from whence it is reported "as if" it were actually there.

Since this process of symbolization is such an important one in the production of symptoms or

*It is important to clarify the fact that in present day clinical usage the term "functional" disorder has taken on a different meaning than its dictionary definition, i.e., a disorder "affecting function but not the structure." Cardiovascular disorders in which function but not structure is affected, e.g., paroxysmal tachycardia or vasodepressor syncope, are usually diagnosed in terms of the physiologic change apparent, i.e., "paroxysmal tachycardia" or "syncope," whereas the diagnostic label "functional" has, in clinical usage, come to be applied primarily to those symptoms in which no functional change is demonstrated and which are, in my experience in most instances, basically symbolic in nature.

complaints, it follows that it is crucial that the clinician understand the symbolic meaning which any symptom, and particularly which any functional symptom, has to the patient. Unfortunately, this crucial point is almost universally neglected in practice, and we do not get the specific information needed to make a diagnosis since we do not learn what the patient thinks is happening to him when he complains of, for example, chest pains, weakness, palpitation, faintness on exertion, or says that he can't get his breath.

It is wise to emphasize at this point that it is important to distinguish between the question, "What does a patient think is wrong with him?" and the somewhat similar question, "Of what use or comfort is the symptom to the patient?" This latter question has to do with what gains (often secondary) accrue to the patient from his symptom, and it should not distract us from getting an understanding of what the primary, symbolic meaning of the symptom may be to the patient.

Let me give an example of symptoms which suggest heart disease but which are symbolic in origin. One very common symbolic meaning of such complaints as shortness of breath, weakness, and chest pain, symptoms which are suggestive of heart disease, is that they express for the patient feelings such as "I am afraid I have a bad or serious disease," or more specifically, "I'm afraid I deserve to have heart disease" or "I deserve to have something bad happen to me." The patient, in short, is expressing feelings of guilt. In our culture chances are very good that if someone is feeling guilty, he is guilty about angry or destructive thoughts or impulses. Let me illustrate by some case presentations.

Case 1.—A combat pilot in World War II, aged thirty, developed feelings of weakness, pressure over the chest, pain around his heart, and later palpitation, about eighteen months before admission, at a time when he was forced into bankruptcy in a business venture because of the perfidy of a previously admired partner, an older man who had fostered and "fathered" the patient. Following the loss of his business, the patient developed the above symptoms and lost interest in work. At times he fantasied meeting his faithless partner on the street sometime, and in telling me of the fantasy stated "I'd kill him if I saw him." The patient's only remembered experience with heart disease occurred when he was in his teens, when his own father died suddenly of heart trouble. The patient became convinced he had heart trouble and consulted several doctors with the symptoms. An internist became his physician, treated him with Pronestyl, and saw him at regular visits. The

patient showed gradual improvement, picked up his life, and found new work. Unfortunately for all concerned, the internist suffered a fatal heart attack six months later. The patient's symptoms immediately recurred and were more severe than ever. He became extremely anxious and overtly depressed. In even a brief medical contact with this man it was quickly clear that he had very mixed feelings, both those of wanting to be cared for and to receive consideration, and those of intense competitiveness with other persons and fear of being exploited by them. These ambivalent feelings were particularly marked in regard to men older than himself or in positions of authority. It was evident that the patient's angry fantasies toward these father figures had boomeranged via his own guilt, with the production of the conviction that he had heart disease.

Case 2.—Sometimes the same set of symptoms represent another kind of guilt, as in the case of a very attractive young mother, a choir singer, who became sexually involved with the choir director and developed symptoms of weakness, palpitation, pressure in the chest, et cetera. She also had the conviction that she had heart disease. Incidentally, as often happens, in this instance there was a secondary gain for the patient in that her sickness prevented her from doing housework, kept her husband reassuringly in attendance on her, and also helped her in rationalizing her behavior.

In other cases, the meaning of heart disease or heart symptoms is more complicated than simply to symbolize the expectation of punishment growing out of feelings of guilt. For example, the symptoms of weakness, fatigue on exertion, and the conviction of the presence of heart disease may, as in the following case, symbolize the patient's feelings about a basic personal weakness and defenselessness in life and be a way of rationalizing a nonparticipation in life.

Case 3.—A pretty, young married woman for many years had symptoms of weakness and shortness of breath on exertion and the firm but unvoiced conviction that she had a bad heart. She was told during adolescence, after an attack of scarlet fever, that she had a heart murmur. She had had a marked exacerbation of her concern with symptoms of weakness, palpitation, fatigue on exertion, and tiredness after her marriage, and particularly when her husband's job necessitated a move to an alien environment. She had episodes of tachycardia, i.e., panic, which were treated medically, and when first seen over a year ago, her conviction that she had an eminently life-threatening heart condition was so fixed as to amount to a delusion. The patient felt uncomfortable and unsafe when forced to go out of her house, and particularly when forced to remain up after her usual 9:30 bed time. She avoided situations or social contacts which might make these things necessary. After eight months of treatment, she became virtually free of symptoms and is now making a much happier social adjustment.

Another kind of symbolic symptom seen commonly in clinical practice and at times labeled as a cardiac neurosis is that seen in a patient who complains of "pain" in the shoulder, down the arm, and into the hand. The specific type of symbolic symptom I am describing almost always occurs on the left, making it a problem to separate it from angina. (Incidentally, more symbolic or functional symptoms are referred to the left than to the right side of the body.) While the patient often refers to this symptom as pain, when this is pin-pointed it usually turns out not to be pain, but is described as numbness or tingling, and almost invariably in describing it the patient rubs his left biceps with his right hand, clenches his left fist, and cocks his left arm back, flexing his elbow as if to strike. Here the symptom expresses partially inhibited rage. One patient I saw with this syndrome several months ago came back about two months later with a broken jaw which he had sustained in a tavern brawl.

Of course, none of these patients come in with a diagnostic tag on them, and in individual situations it may be very difficult to decide whether a given symptom is symbolic or not. For example, it may be difficult to decide whether a given patient is having angina or the inhibited rage just described, or whether the patient is having attacks of anxiety at night with the sensation of smothering, or is having paroxysmal nocturnal dyspnea. This differentiation is apt to be particularly difficult when there are present physical or laboratory findings which might possibly explain the symptoms, and of course it is not at all unusual to get symbolic symptoms such as dyspnea, palpitation, or pain added to the picture of a patient with organic heart disease. It is important that, as physicians, we always have such a clear picture of the patient's symptoms that they will not be attributed to abnormalities present on physical examination or laboratory tests unless it is likely that these are in fact causing them. The more dramatic the finding, the more likely it is that we will use it as an explanation for symptoms which it does not produce, as in the following case.

Case 4.—A garage mechanic, aged forty-four, complaining of fatigue, inability to withstand the rigors of work, and inability to support his family, was found to be manifestly depressed and more than a little paranoid when examined as an outpatient. Because of a low pulse rate an electrocardiogram was obtained during his medical workup, which revealed a complete heart

block. As the result of concerted medical quizzing and diagnostic procedures, he learned he had heart trouble, and as he became medically sophisticated, his complaint changed to "fainting and fainting spells." In time his psychologic and social status deteriorated. The ultimate medical consensus was that the heart block was a congenital, totally asymptomatic lesion. Nevertheless, because of his basic personality disorder the patient's concept of himself as a cardiac cripple has never wavered, although he has had supportive psychiatric and medical care for years since then.

Less dramatic findings than a complete heart block, such as extrasystoles, systolic murmurs, or borderline electrocardiographic changes more frequently act as diagnostic red herrings. As Alvarez has said, we need a course in medical school on disregarding positive findings that can't explain syndromes¹

It is important to emphasize that as far as the patient is concerned it is not knowledge of findings of this type which in itself makes a patient pathologically anxious. Rather his anxiety comes from other sources, and any changes in function or insignificant somatic findings present may serve as convenient and socially acceptable hooks on which to hang his feelings. Thus, for example, all of us have had transitory, almost subliminal pains or sensations in the chest. When these occur on the right side of the chest we usually ignore them. When they occur on the left side of the chest, we ordinarily give them only a passing thought. However, if at the time this left-sided pain occurs we are anxious about some other problem in our life we may well displace this anxiety and thus become concerned about this chest pain and the likelihood of heart disease. One of the characteristics of anxiety is that in its naked, or "free floating" state, it is so uncomfortable that we deflect or modify it quickly, often by displacing it from its original source.

In clinical practice it is usually not too hard to be reasonably sure why the anxiety was displaced to a particular region or organ. Sometimes the choice of symptom results from such factors as some recent or dramatic illness of a relative, friend, or public figure, President Eisenhower's coronary occlusion being a case in point. Or it may result from a remembered illness in the patient's life or in the lives of the parents or siblings, or from the sensations caused by the patient's own body processes, especially if these have been modified or amplified by emotions.

Sometimes, too, the doctor may unknowingly di-

rect the patient's emotional reaction toward one organ or another. Insofar as the problem of cardiac neurosis is concerned, this is particularly apt to occur when the patient comes in in a panic or an acute anxiety state, and the doctor cannot help but be impressed by the pounding heart and rapid pulse and may be unwilling to state categorically that there is nothing wrong with the heart. I remember doing this when I was in rural practice and a young man came running into the office in panic just at the supper hour, complaining, "Something's wrong with me." His bounding pulse and forceful apex beat with associated extracardiac sounds made me a little uncertain, and I must have communicated this to him in examining the heart, for by the next day the patient's anxiety was no longer free floating, but had channeled into a near conviction that he had a serious heart disease. We doctors should not blame ourselves too much when this happens, since free, unmodified anxiety is so uncomfortable for a patient that some alteration in it is going to result in any event.

Regardless of the individual variation in the pathway of symptom formation, the essential point is that we need to know all we can as to what the symptom means and why a particular one is "selected." In any diagnostic process it is necessary that some direct connection be established between the suspected pathologic condition and the things the patient complains of before the diagnosis is considered certain. This of course is just as true in regard to psychosomatic diagnoses as it is in regard to other diagnoses, since a diagnosis which rests simply on the fact that there are present both symptoms not otherwise explained and significant emotional conflicts or problems of living, without any direct association being established between them, is a very shaky diagnosis indeed. It can be compared to the practice of assuming that a nondescript abdominal pain is caused by the gallstones which are demonstrated incidental to an x-ray survey of the gastrointestinal tract. This brings us to the second area of consideration, namely a discussion of a few of the emotional reactions resulting when people learn they have heart disease.

Psychologic Reactions to Organic Heart Disease

Grief is the one completely appropriate and virtually essential emotional reaction in a patient who learns he or she has organic heart disease (or for

that matter any other disabling disease). Grief is a healing process and may be regarded as a homeostatic mechanism, since it has as its result the restoration of emotional equilibrium after we have been bereft. It is psychologic healing of the experience of loss or separation and represents the "scabbing over" of a wound and the recognition and acceptance of the loss. Whether the loss be that of a friend, an idea, a part of the body, a part of life, or of health, the process is essentially the same. We have to hold the loss up and look at it, and in doing so recognize the implications of the loss. For example, in the case of heart disease this may mean recognizing the loss of an avocation, say hunting or hiking, or loss of youth or possibly of work. When we do this we feel sorrow and the healing flow of tears. Thus we draw back to ourselves for reinvestment in another part of life or another person a large part of the emotional investment we had in the thing we have lost.

One reason for emphasizing the normalcy and utility of grief is that until a patient has the healing experience of grief or "works through" his feelings about his heart disease, he has not reached his maximum recovery. To be sure, patients who have suffered a loss, such as the loss of vocation because of a myocardial infarct, sometimes put off the painful working through of grief by repressing or distorting the emotion or the experience. In doing this by one device or another, they wall off an important part of themselves from any real participation in living until, at a later date, a delayed grief reaction is precipitated. However, until the grief is worked through, there remains a tender area of psychologic inflammation, sometimes hidden, a "collection of emotional pus,"³ potentially capable of spreading or disabling the patient by psychologic symptoms or illness.

Moreover, it is important to distinguish between the healing release of grief and the resentful reaction of "grieving" which is a kind of nursing one's misfortune to keep it alive, and in which there is no real acceptance of loss but primarily the angry reiteration of the feeling, "Why did this have to happen to me?"

Because it is usually the healthiest of emotional reactions to organic illness, and because it is self-healing, grief is somewhat set apart from other emotional reactions to heart disease. What reactions other than grief a patient may have to heart disease will depend on many factors, such as the

circumstances under which the disease develops, the time in the patient's life, the kind of person the patient is, and his habitual patterns of handling his problems, among others. We have all seen a variety of such reactions, but in the time available I will be able to discuss only one or two to illustrate the distinctions between this group of psychologic reactions of illness and the functional symptoms described above. For example, heart disease must take its place along with diabetes, cancer, et cetera, as one of the conditions which is likely to "trigger" a depression of middle life. These conditions all tend to remind us of our own perishability, or at least that our life is passing, and thus to activate those potentials of unhappiness which are the inevitable residue of whatever neurotic compromises and adjustments we have made with the realities of life.² One neurotic adjustment to life commonly seen is that of living in a somewhat contractual way wherein the proposition is that good behavior, i.e. virtue, will ultimately be rewarded. This widespread idea often is the keystone of a self-sacrificial life, though it runs contrary to biblical injunction that "virtue is its own reward." If this contract were written, it might read something as follows: "I'll live by these rules such as self-sacrifice, conscientiousness, loyalty, et cetera, and in return I will be rewarded by such things as approbation, status in the community, and possibly even protection from the vicissitudes of life, such as ill health." Although this may be the way we are trained as children, in adult life other persons with whom we associate, as well as the events of our life and our times, are not actually a party to this contract. Consequently, while we may uphold our part of this bargain, our environment is not likely to. Ultimately we feel cheated and resentful. A diagnosis of heart disease is apt to set off such a reaction, as it may bring home to a patient that this contract of his is not going to be fulfilled, and leave him with the feeling of having somehow been robbed. Of course, this feeling is not apt to be expressed directly; rather, the patient clinically appears depressed.

Another reaction to the diagnosis of heart disease sometimes seen is the anger and defensive belligerence of the person who has built his personality around such compensatory defenses as bravado and an assumed invincibility. This kind of person often feels that he is alone and that the world about him is a kind of jungle. Such a

person is a "paper tiger," who uses bravado to ward off inner feelings of his own vulnerability and loneliness, and who, when cardiac invalidism or disability threatens to puncture his defenses, cannot help but react with anger to the threat.

Surgical treatment of heart disease is becoming more common; therefore, I would like to comment on some of the emotional implications of surgery in heart disease. We would assume that a procedure would prolong life and make it more active and comfortable would be welcomed without reservation, and would not cause emotional difficulty. In most cases that is true, but in others the improved physical status may bring problems and produce psychologic stress. Consider the following patient, one I have seen recently.

Case 5.—A married woman, aged thirty-eight, mother of three children, with a long history of severe and worsening episodes of cardiac decompensation caused by rheumatic valvular heart disease, had had a successful and life-saving mitral commissurotomy eight months previously. Rheumatic valvular disease had developed while the patient was in her teens, but it was not until she had been married several years and had had recurrent bouts of rheumatic fever that this in any way affected her life. She had led an active life until forced into increasing invalidism by symptoms for the five or six years prior to surgery. The patient had an unexpressed conviction that the inexorable progression of her symptoms and disability had resulted from the demands on her of her marriage, and particularly of her motherhood. Despite a good functional result after surgery the patient had not enjoyed her improved health, but rather had overemphasized her residual cardiac disability. In fact, there was reason to believe that she had precipitated an episode of decompensation by eating large quantities of salted popcorn, although she had carefully observed a restricted salt intake for years previously.

Here, then, is another type of psychosomatic problem in heart disease. This patient, having capitalized on her invalidism or reconciled herself to it by getting certain emotional gratifications out of it, in this instance prestige in the community and a tyrannical position within the family because of her martyrdom, found it difficult to relinquish this role for the more active participation in life offered her by new surgical techniques. This was true despite the fact that before the operation she had ostensibly been anxious to have it.

A Recommendation for Managing Psychosomatic Problems

Successful management of psychosomatic problems is based on many medical skills and attitudes

including the doctor's knowledge about people and the problems of living as well as his capacity to relate to other people and to use himself in such relationships as an instrument of treatment. However, it is also based on the doctor's ability to make a specific diagnosis regarding the symptom, or to come to an incisive understanding of the patient's complaint. Because this need for specific diagnosis of symptoms is frequently overlooked, and because the problems which arise in caring for patients with psychosomatic disorders are often traceable to just this point, I wish to discuss diagnostic specificity as an aid in the management of psychosomatic disorders.

Making a specific diagnosis of the cause of symptoms (after the manner described earlier in this paper) is largely a matter of skillful history taking or medical interviewing, and ordinarily can be readily accomplished. However, in clinical practice, as was noted earlier, more often than not a specific diagnosis as to the nature of a functional symptom is not made. Consequently, from the outset the stage is set for inconclusive therapy and frustration for doctor and patient.

This disregard for diagnostic accuracy is by no means confined only to functional symptoms. Rather, it reflects a fundamental fault in our medical habits of diagnostic thinking and is not something that crops up only in relation to psychosomatic symptoms, although it may be more obvious there. The fault I refer to has to do with doctors' failure in many instances to get an adequate understanding of patients' symptoms because of perfunctory history taking. The result is that they must rely primarily on findings to make a diagnosis or else rely on the self-limited character of the disease itself and thus avoid the necessity for making a diagnosis on which to base treatment.

In theory, a diagnosis is made by the following process: first, by means of a medical history or interview, we get a clear understanding of the patient's symptoms, their development, and then get what information we can from the physical examination and indicated laboratory procedures. Practically, all too frequently we get from the patient by history only a very general idea of what his trouble might be. Then we pass on to the physical examination in the hope of discovering an answer and then throw out a kind of diagnostic

dragnet of laboratory and x-ray procedures in the expectation that something may turn up. Having failed to exploit the potential for accurate diagnosis available in getting a history, we are all too often left with only the relatively meager and sometimes misleading data obtained from physical, laboratory, and x-ray findings to go on. The result is often a diagnostic impasse.

The reasons for the prevalence in medicine of this unrewarding type of diagnosis are too complex to be discussed here and will be presented in a later paper. Suffice it to say that in addition to the problems of communication involved, there is also the fact that the need for specific symptom diagnosis is generally unrecognized. Consequently, we are likely to accept a patient's complaints at face value, making little attempt to have him spontaneously define or amplify them further. Often at this point the doctor makes an interpretation or guess as to what a patient means by what he says. Instead, the patient should be encouraged to explain and not be permitted to evade sharp definition of his symptoms. Many times patients say something like "It's just a sort of a pain. *You know,*" and the doctor finds himself nodding in agreement and passing on to another question when, in fact, he doesn't know at all. What is required is a nondirective type of history taking which follows the patient's train of thought, but what often takes place is a directed type of question and answer interview which necessarily follows the questioner's associations.

To disregard partially our best source of information,⁴ namely the things the patient can tell us about his own symptoms, is, to say the least, inefficient. More efficient management of psychosomatic problems must rest on specific diagnosis of symptoms, which in turn must rest on adequate communication with the patient.

The Diagnostic Importance of Uterine Artery Size

JOHN L. FALLS, M.D.
Red Wing, Minnesota

ALTHOUGH cases of uterine artery hypertrophy have been reported from time to time, usually in conjunction with vascular anomalies, vascular tumors,¹ or neoplasms of the uterus,² the diagnostic value of fluctuation in the caliber of these vessels has not been fully exploited by clinicians. Particularly, little attention has been given to their behavior during pregnancy, yet here is where assessment of their size can be of daily clinical usefulness.

In 1952, while interpreting a large series of iliac artery angiograms, Borell and Fernstrom³ became interested in the marked variation in uterine artery size. In this and subsequent studies⁴⁻⁷ they made many important observations on the response of the uterine vasculature to the ovarian hormones and to normal intrauterine pregnancy, tubal ectopic pregnancy, hydatidiform mole, and choriocarcinoma. To determine the extent to which uterine artery size is governed by ovarian hormones, they selected a group of amenorrheic women in whom hormone excretion tests and cytologic studies revealed an absence of endogenous estrogen. Iliac artery angiograms were then made before, during, and after ovarian hormone replacement therapy. In summarizing their results, these authors state that "as the uterine arteries were the only blood vessels showing an alteration in width, they are apparently particularly sensitive to hormone action, irrespective of whether the stimulus is direct or indirect." After studying the angiograms in cases of early pregnancy, they found that uterine artery hypertrophy became clearly established in the second month. They also observed that in tubal ectopic pregnancies, the adnexal branch of the homolateral uterine artery was as large as the ascending portion of the uterine artery from which it was derived, whereas in normal intrauterine gestation, the adnexal branches remained unchanged, being of much smaller size than the parent vessel.

Finally, angiographic studies were made of hydatidiform moles and choriocarcinoma. In addition to a striking increase in the caliber of the uterine arteries, a characteristic mottling was noted to occur within the uterine wall itself, apparently the result of unusually large arteriovenous shunts which exist in this type of conceptional abnormality.

As a result of the foregoing studies, and others involving pelvic angiography in a variety of gynecologic disorders, Borell and Fernstrom³ suggest that greater diagnostic accuracy awaits the clinician who utilizes this method of visualizing the uterine circulation. Of what they are seemingly unaware is that the uterine arteries are easily accessible to the palpating finger, and fluctuations in their caliber can be detected accurately and without expense or danger to the patient by careful pelvic examination. During the past four years it has been the author's practice to palpate for the uterine arteries routinely in the course of bimanual examination, and the observations made form the basis of this report.

The ascending branches of the uterine arteries are located at two and ten o'clock in relation to the circumference of the cervix and two to four centimeters above the level of the external os. They are most readily palpated during rectovaginal examination, when the cardinal ligament is compressed between the two examining fingers much as it is grasped by a hemostat during vaginal hysterectomy. Especially is this true if the uterus is retrodisplaced. Ordinarily, in the absence of pregnancy or pelvic pathology, the uterine arteries are either not palpable at all, or only faintly so. However, under the influence of any factor which increases the metabolic activity of the uterine tissues, these vessels quickly enlarge to a degree commensurate with the increased metabolic demand. The most common such factor is conception. There is probably no tissue in the human body more metabolically active than the uterus as it is being invaded by embryonal trophoblast,

Presented before the Minnesota Obstetric and Gynecologic Society, Rochester, September 22, 1956.

and the demand imposed upon its vascular channels of supply is both immediate and imperative. Hence, it is not surprising that by the end of the fourth week of conceptional age, that is when the menses is approximately two weeks overdue, the uterine arteries usually become distinctly palpable, and not infrequently exhibit a bounding pulsation as clearly defined as the radial pulse. This arterial hypertrophy precedes the appearance of Hegar's sign, Chadwick's sign, and softening of the uterus, for these are the later manifestations of passive venous congestion.

A very interesting observation is the behavior of the uterine vessels in the presence of tubal ectopic pregnancy. The uterine artery on the homolateral side is found to be of distinctly larger caliber than the contralateral vessel. Again this is not surprising, for tubal ectopic pregnancy in the human is physiologically analogous to unilateral pregnancy in one horn of the uterus duplex in lower mammals. As Reynolds⁸ has shown in rabbits, the gravid uterine horn hypertrophies much more quickly and extensively than does the nongravid horn, and the very foundation of this uterine growth is the preceding vascular hypertrophy. The adnexal or anastomosing branch of the ascending portion of the uterine artery leading to the developing ectopic conceptus is its principal arterial supply, and usually this branch can be felt as a strongly pulsating vessel immediately subjacent to the tender tubal mass. This asymmetric hypertrophy of the uterine vasculature can be a valuable diagnostic aid in the evaluation of unruptured tubal ectopics. However, it is in no sense pathognomonic, for other causes of localized increase in tissue metabolic rate, e.g., infection or rapidly growing neoplasm, can induce similar regional arterial hypertrophy. Therefore, interpretation of this sign should always follow careful correlation with the other clinical and laboratory findings. When this is done, the degree of diagnostic accuracy can be considerably enhanced, as illustrated by the following case report.

Case Report

The patient (Mrs. A. M. P., Hospital No. 321-899) was a twenty-four-year-old gravida 11, para 1, whose only previous pregnancy followed an uneventful course to a normal spontaneous delivery in 1947. A six-year interval of involuntary sterility followed, during which time the menstrual periods were normal.

On May 13, 1953, she was admitted to the University

of Illinois Research and Educational Hospital with the complaint of having had some intermittent cramping suprapubic pain two months previously and again four days prior to admission. There had been no menstrual aberration through the time of her last normal period, which occurred twenty days prior to admission. However, with the recurrence of the suprapubic cramps four days before admission, she had noticed some spotting. She came to the hospital not because of distress, but out of curiosity about the spotting.

Examination revealed a well developed and nourished Negro female of stated age who was alert, comfortable, and co-operative. The significant findings were slight tenderness on deep palpation in the right lower quadrant without rebound tenderness or rigidity, and a slightly tender right adnexal mass. This mass was fusiform, about five centimeters in length, and not freely movable. The uterus was estimated to be 120 gram size. It was firm, symmetrical, and motion of the cervix caused no distress. The right uterine artery was palpable but the pulsation was of only moderate intensity. The ascending branch could be traced upward to the ventral aspect of the right adnexal mass, with no appreciable alteration in its width as it was followed distally. The left uterine artery was not palpable, and the left adnexa were normal. The cervix was healthy in appearance, and there was a minimal amount of old blood in the posterior fornix. The culdesac was vacant and there was no regional hyperthermia anywhere in the pelvis.

Laboratory findings were as follows: Hemoglobin 13 gm., hematocrit 44, RBC 4.12 million, WBC 9,000. A catheterized urine specimen contained no albumin, sugar, or bile, but gave a positive urobilinogen reaction up to 1:20 dilution. Microscopically, it was negative. Cultures of the urethra and cervix were subsequently reported negative for *Neisseria gonorrhea*. The clinical impression at the time of admission was unruptured right tubal ectopic gestation with *in situ* death of the conceptus. The patient was kept on the ward under observation for the next twelve days, during which time she was frequently re-examined. By the end of this interval, all abdominal tenderness had disappeared, the right uterine artery had slowly regressed to the point where it could no longer be palpated, and the right tubal mass exhibited only negligible discomfort on compression. Its size remained essentially unchanged however.

Because ampullary tubal abortion could not be ruled out, laparotomy was undertaken on May 22, 1953. On entering the pelvic cavity, approximately fifty cubic centimeters of old blood was found in the culdesac. The omentum and rectum were adherent to a right tubal mass which was four by five by six centimeters. The corpus was about one and a half times normal size, and direct palpation of the uterine arteries and the ovarian arteries revealed no hypertrophy on either side. Right salpingectomy was performed, the tube hardened in Keyserling's solution for four days, and then the specimen was sectioned with a sharp microtome blade. A five millimeter embryo was found completely surrounded by an old blood clot which filled the amniotic cavity. Outside the amnion, an organizing hematoma was found to have infiltrated all layers of the tubal wall. On micro-

scopic examination, degenerating chorionic villi and sheets of syncytium were found throughout the muscularis. The pathologic diagnosis was: Ectopic pregnancy, missed abortion type.

A case such as this is representative of an untold number of ectopics each year which escape detection, but with no serious consequences. Had this patient not been subjected to surgery, the ectopic pregnancy would undoubtedly have undergone progressive hyalinization to become merely fibrous thickening in the right tube, such as are not infrequently encountered as incidental findings during the routine examination of gynecologic specimens in the surgical pathology laboratory. It is tempting to speculate that had she been given antibiotics during the period of observation, the progressive decrease in tenderness might have been erroneously construed as confirmation of an inflammatory mass responding to therapy. The key to the correct diagnosis in this instance was the behavior of the uterine vessels in relation to the other clinical findings.

After encountering the above case, subsequent cases of ectopic pregnancy were examined periodically during the postoperative course. It was found that the arterial hypertrophy usually had disappeared by the end of seven to ten days. This observation suggested the possibility that regression in uterine artery size might be of value in diagnosing missed abortion, and clinical observation bore this out, but only in cases where the patient had been examined prior to the occurrence of intrauterine death, so that comparison of the arteries before and after could be made. In such circumstances, arterial regression usually precedes noticeable diminution in uterine size. This can be particularly helpful in evaluating cases in which obesity of the patient or retrodisplacement of the uterus make accurate appraisal of its size difficult. The diagnosis of missed abortion should never be founded upon subjective signs alone, and though decrease in uterine artery size may early suggest the possibility of intrauterine death, more objective criteria must be awaited before intervention is undertaken.

Though the author has not had the opportunity to confirm it, regression in uterine artery size should theoretically have clinical usefulness in the follow-up evaluation after removing a hydatidiform mole, because prior to evacuation, the arterial hypertrophy has been shown to be maximal. Failure of arterial regression to occur after emptying the uterus, or partial regression and then re-expansion would be cause for concern regardless of hormone titers.

In summary, it should be re-emphasized that the uterine arteries respond dramatically to any rapid increase in metabolic demand within the tissues which they supply. Both the speed and the degree of their expansion are unique, partly because of the singularly dynamic growth patterns of the uterus compared with other organs of similar size, and partly because of their intrinsic and specific sensitivity to the ovarian hormones. With practice, the changes in the uterine vasculature can be easily and accurately followed by rectovaginal palpation, and when correlated with the other clinical and laboratory findings will prove to be a rewarding diagnostic aid in solving many of the common problems in the practice of obstetrics and gynecology.

Review of Coroner's Cases in Olmsted County, Minnesota (1924-1953)

FRANK H. DE LAND, M.D.
WARREN A. BENNETT, M.D.
THEODORE O. WELLNER, M.D.
Rochester, Minnesota

THE OFFICE of coroner is our legacy from the English system of jurisprudence. It was created in medieval times, and the name derives from *custos placitorum coronae*, or "keeper of the pleas of the crown" within a county. According to some authorities, it originated under King Athelstan in the tenth century; other authorities date it from the articles of the eyre, or *capitula itineris*, in the thirteenth century. Even at that time, certain qualifications, such as knighthood and property ownership, were required for office. Today in England the coroner usually is a barrister, and the coroner's physician is a pathologist, and these are appointive positions.

The Current Scene

Although we adopted the office of coroner, we failed to stipulate the necessary qualifications, and in more than two thirds of the states this position is an elective office. The only statutory requirement is that the candidate be a registered voter, and the only practical requirement is that he possess the ability to obtain enough votes for election. Aside from the several states or parts thereof that have adopted the medical examiner's system, in 1931 only three required that the coroner be a physician.¹ As a result, the coroner in most instances has had no specific training, either medical or legal.* It is questionable, therefore, whether such a person has the judgment to determine if further medical investigation of a death is warranted, except in the most obvious of circumstances.

Dr. DeLand is Fellow in Pathology, Mayo Foundation; Dr. Bennett is in the Section of Pathologic Anatomy, Mayo Clinic and Mayo Foundation; and Dr. Wellner is Coroner, Olmsted County, Rochester, Minnesota.

The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

*In Minnesota, no coroner may practice as an attorney in any court (Section 387.13).

To the general public, the importance of an elective office bears direct relationship to its position on the ballot. Since the office of coroner usually appears toward the end of the ballot the occupant thereof is considered relatively unimportant. However, his duties and powers are quite broad. Specifically, they vary from state to state, but generally the primary duty of the coroner is to determine the circumstances surrounding violent deaths and those from natural causes, with no previous medical history. The coroner has the authority to order necropsy, bacteriologic and chemical analyses and inquests. In some states he must obtain court permission for a necropsy. To the public he is best known for his work in criminal cases; however, such cases actually comprise only a small segment of his duties. The investigation of violent deaths other than homicides and suicides has become increasingly more important as legal medicine has assumed greater proportions in this country. This category would include traffic fatalities, industrial accidents and the many other types of accidental death. In all phases of medicine the ultimate aim is prevention rather than treatment; therefore, it is the coroner who is in the position to study these cases and to help formulate preventive measures.

Coroner's System in Olmsted County

Olmsted County, Minnesota, has had a satisfactory coroner's system for a number of years. The office of coroner has been held by a physician for seventy years (with the exception of an eighteen-month period), and the coroner's pathologist has been the pathologists of the Mayo Clinic for fifty years. Although this arrangement is unique for a county of 50,000 population, most counties of this size have physicians who could occupy the coroner's office and at least one pathologist who could act as coroner's physician.

Nature of Present Study

Since Olmsted County has had a progressive system for a number of years, it was felt that a study of the coroner's work would prove worth

Fig. 1. Coroner's cases, Olmsted County, 1924 through 1953. Average number per year in five-year intervals.

while. This investigation was undertaken with twofold purpose: to demonstrate the quality of work which is possible, and to determine whether any conclusions could be reached on the basis of such a study. For example: What are the types of injuries sustained in traffic accidents? Is there any correlation between the seating position in an automobile and the injuries received in an accident? At what age is suicide most prevalent? What are the common causes of accidental poisonings? These and other questions perhaps can be answered by such an investigation.

Work Load

During the thirty-year period of this study, 1924 to 1953, inclusive, a total of 1,800 cases were investigated by the coroner, an over-all average of sixty per year. The number of cases per year varied from a low of thirty-one in 1926 to a high of 103 in 1951. Yearly variations were

fairly marked; therefore, it was necessary to divide the thirty-year span into five-year intervals for better representation. Figure 1 shows the average number of cases per year for the five-year periods.

Fig. 2. Coroner's cases, Olmsted County, 1924 through 1953. Percentage of cases in which necropsy was done. Average per cent per year in five-year intervals.

From 1924 to 1928, inclusive, there was an average of forty-two cases per year, and then for the next twenty years the average yearly rate was rather constant, varying from fifty-six to sixty per year. In the postwar period of 1949 to 1953, the yearly average increased to ninety-two. When the census variables, both resident and transient, are taken into consideration, it is found that the rate of coroner's cases is approximately constant for the first twenty-five-year period of this study, meaning from 1924 to 1948, inclusive. However, in the last five-year period, the rate increased. We feel that this greater incidence is due in large part to increased interest and realization of the importance of investigating deaths from unknown causes or trauma.

Postmortem Examinations

Figure 2 is a graphic representation of the percentage of coroner's cases in which postmortem

examinations were performed. This figure likewise demonstrates a slight increase during the last five years. The average percentage for the thirty years is fifty-nine, and the deviation is

in which necropsy was done slightly exceeded the number in which necropsy was not done, but in the last five-year period the ratio was 3:1. Figure 4 shows similar curves calculated for necropsy

Suicides	134	132
Homicides	19	2
Total	503	280

just as much below this average as it is above it. This compares very favorably with the necropsy percentage sixty-two in Los Angeles County, California, which is generally considered to have an excellent coroner's system.² The greatest increase in total investigations in the coroner's office occurred during the tenure of the present coroner.

These cases were divided into two large groups: persons who died of natural causes and persons who died from violence of any type. Figure 3 indicates the deaths due to violence, showing the number of cases in which necropsy was performed and those in which it was not done. During the first twenty-five years the number of cases

in deaths due to natural causes. During the first twenty-five years the number of cases in which necropsy was done was approximately equal to the number in which it was not done, and in the last five years there was an increase in the number of postmortem examinations, but the increase was not nearly so marked as that in the category of deaths due to violent causes (Fig. 3). This clearly demonstrates the increasing importance attached to the investigation of deaths due to violence.

Deaths Caused by Violence

First, we should like to consider those cases of death from violent causes. In this category there were 503 cases in which postmortem examination was performed. These were distributed as shown in Table I. Seven-tenths of the deaths were caused by accidents, meaning that no criminal intent was involved, either to oneself or to someone else.

Automobile Accidents.—More than half of the accidental deaths were due to traffic accidents. The incidence of traffic fatalities varied from 3.4 per cent for the period 1924 to 1928, inclusive to 11 per cent per year for the period 1949 to

1953, inclusive. The relative rate by five-year periods from 1924 to 1948 was constant when the population change is taken into account. However, there was a marked increase for the five-year period 1949 to 1953, and this we feel cannot be accounted for on the basis of increased accident rate alone, but rather, on the enlarging concept that such fatalities should be investigated by the coroner. Hence, more such accidents are coming under the coroner's jurisdiction. There were seventy automobile-pedestrian accidents. The most common injuries suffered by the pedestrian were fractures of the skull, extremities and ribs, lacerations and contusions of the brain, and hemorrhage into the lungs. Collisions of automobile with automobile numbered seventy-two. The most common injuries resulting from this type of accident were fractures of the ribs, skull and extremities, contusions of the brain, lacerations of the great vessels, liver and spleen, and hemorrhage into the lungs. There were thirty-four fatalities resulting from single-automobile accidents. The most common injuries under these circumstances were fractures of the ribs, extremities and skull, and laceration and hemorrhages into the brain.

Table II is a summary of all the injuries encountered in these three groups. It will be noted that in all three of these types of traffic accidents, the ribs, extremities and skull are the predominant bones fractured. Injuries to the brain are of about the same frequency in all three. However, injuries to the cardiovascular system are more common in collisions between automobiles. This undoubtedly is due to the sudden deceleration in head-on collisions. A surprising finding was the incidence of injuries to the adrenal glands: 13 per cent of 176 cases. It is impossible to ascertain how many instances of adrenal insufficiency were occasioned by adrenal damage and the stress of injury, but it can be speculated that supportive therapy may have saved some of the persons concerned. When one adrenal body is injured, it is possible that the other one cannot compensate rapidly enough, in view of the stress of other severe injuries.

Injuries to drivers and passengers were studied in the category of collisions of automobile with automobile. There were seventy-two cases of this type (Table II). The fatalities in this group were divided evenly between driver and passenger. Both drivers and passengers received essentially

the same types of injuries, with the exception of skull fracture. Passengers received twice as many fractures of the skull as did drivers. Undoubtedly, the basis for this difference is the fact that the

steering wheel protects the driver from being thrown against the windshield. This is one of the reasons why safety authorities advocate the use of safety belts.

Deaths resulting from traffic accidents in which the occupant was forcibly thrown from the vehicle also were tabulated. In collisions between automobile and automobile, 10 per cent of the seventy-two deaths, and in the single-automobile accidents 53 per cent of the thirty-four deaths, occurred in this manner. In the second group, fourteen persons were killed by crushing as the vehicle rolled. In one case the driver was thrown 143 feet ahead of the automobile, which continued to roll until it crushed the victim. Why a driver or passenger should be thrown from the car five times as frequently in a single-automobile accident as in a collision between automobile and automobile is difficult to answer. Perhaps, in the case involving the single automobile, it is the element of surprise, or perhaps there is greater tendency for the car to roll than when two automobiles collide. In discussing some of the more recent accidents with the investigating officers, it was interesting to discover that persons who were not hurled from the automobile usually were not

killed or even seriously injured. This is certainly a telling argument for the development of better safety latches on automobile doors and also for the use of safety belts.

p.m. probably is related to heavier "rush-hour" traffic, both pedestrian and automobile, and to the increased number of school children playing at this hour. The peak reached at 8:00 p.m. cer-

Fig. 5. Coroner's cases, Olmsted County, 1924 through 1953. Pedestrian fatalities and persons killed in automobile traffic accidents, according to hour of occurrence.

Of the seventy pedestrians killed in traffic accidents, twenty-seven were children under the age of ten years. Three times as many pedestrians were killed in the first decade of life as in any other. In contrast to these findings, it is noted that the peak of fatalities among victims of automobile accidents occurs in the second and third decades. The incidence in those two decades is more than double that of any other age group. Only two children less than the age of ten years were killed in automobile accidents.

The hour at which fatal traffic accidents occurred was known in eighty-eight automobile accidents and fifty-four accidents involving automobiles and pedestrians (Fig. 5). There are two marked peaks in the curve calculated for fatalities resulting from automobile accidents, one at 6:00 p.m. and another at midnight (Fig. 5). The peak reached at 6:00 p.m. probably is related to heavier traffic and fatigue at the time when people are returning home from work. The peak reached at midnight undoubtedly is influenced by such factors as fatigue, speed, alcohol and others. The curve calculated for pedestrian fatalities also shows two significant peaks, one at 5:00 p.m. and a second at 8:00 p.m. The peak reached at 5:00

tainly is due to decreased visibility because of darkness.

We might summarize the facts that have been learned from this study of traffic fatalities: (1) more traffic fatalities are being investigated by the coroner's office; (2) fractures of the skull, ribs and extremities, and lacerations or contusions of the brain were the common injuries in all types of traffic fatalities; (3) cardiovascular injuries seem to be more common in accidents involving sudden deceleration (collisions); (4) adrenal injury often occurs, and may be one of the underlying causes of shock; (5) in fatal automobile accidents, passengers received skull fractures more often than did drivers; (6) the inefficiency of automobile door latches under the stress of impact is a common cause of occupants' being thrown out and fatally injured; (7) fatalities in automobile accidents occur more commonly during the evening "rush hours" and at midnight; and (8) pedestrian fatalities also occur more commonly during the evening "rush hours" and shortly after dark.

Deaths from Falls.—There were thirty-seven cases of accidental death caused by falls, and the

height of these falls varied from ground level to thirty feet. More than 50 per cent of the victims died from fractures of the skull and lacerations of the brain. Eleven persons died from compression or laceration of the spinal cord as a result of either fracture or dislocation in the cervical part of the spinal column, or both. All these victims struck the ground on the head, back of the neck or feet. Two deaths were caused by rupture of the aorta, and in one case the rupture was so small that the victim lived for one hour. In one instance, a fall resulted in rupture of the base of the mesentery, and death was caused by retroperitoneal hemorrhage, no other lesions being found. Two interesting cases in which falls were involved might well have been listed as cases of accidental death (with all insurance implications), had not postmortem examination been performed. In one of these, an elderly man was seen to fall on an icy sidewalk, and was pronounced dead on arrival at the hospital. Examination revealed that massive pulmonary embolism actually was the cause of death. In the other case, the victim fell down a flight of steps and was pronounced dead immediately. Coronary occlusion was found at necropsy.

Accidental Poisoning.—Accidental poisoning as a cause of death occurred in thirty-one cases. One third of these deaths were due to carbon monoxide poisoning; all the victims were men except one. The source of the carbon monoxide was either automobile exhaust or heating units. There were nine cases of acute alcohol intoxication, both methanol and ethanol, and all the victims were men. Postmortem examination in these cases revealed either edema of the brain or edema of the lungs. Four children died from the accidental ingestion of poisons. Three of these poisons were arsenical compounds (insecticides) and one was a phosphorus-containing compound (rodent exterminator).

Deaths from Asphyxia.—Seventeen fatal accidents were classified as having been caused by asphyxia. Most of these deaths were brought about by aspiration of a food bolus or a foreign body. Several infants were thought to have smothered in bed clothing. Further investigation probably would have proved an underlying etiologic basis other than asphyxia.

Miscellaneous Deaths.—The remainder of the accidental deaths were distributed as is shown in Table I, which is self explanatory. The number of cases in each category was too small to permit any generalizations.

Suicides.—There were 266 suicides during this thirty-year period. For the first twenty-five years, the percentage of cases in which necropsy was done was fairly constant, averaging slightly less than fifty, during the last five-year period the average yearly percentage of cases of suicide in which necropsy was done increased to seventy-five. Our study shows that twice as many males as females committed suicide. The ages ranged from sixteen to ninety-one years, with 50 per cent of the victims being in the age group of forty to sixty years.

1. Firearms.—Men committed suicide with firearms three times as often as did women. Four of five times a small-bore pistol or rifle was used, and the most common site of injury was the head, with fracture of the skull and lacerations of the cerebral hemispheres and brain stem. Shotguns generally were used to inflict wounds of the abdomen and thorax, and in all our cases there was mutilating damage to the heart.

2. Sharp Instruments.—Men also used sharp instruments (razors and knives) three times as often as did women. Except in one instance, all the injuries were lacerations of the throat. Death usually was caused by severance of the jugular veins, and in one case the wound was sufficiently deep to lacerate the aorta.

3. Poisons.—Women committed suicide by ingestion of poisons twice as often as did men. The most commonly used poison was one of the barbiturates, and nearly all deaths due to these drugs have occurred since 1940. There were fifteen cases of lysol poisoning and eight cases of arsenic poisoning, all of which were recorded prior to 1940. Other agents used were strychnine, halides, chloroform and carbon monoxide.

4. Leaping to Death.—Women jumped to their death twice as often as did men. Most of these, of course, died instantly; however, several lived for a few minutes to an hour, even though they had fallen from a height as great as five stories. Besides multiple fractures of bones, lacerations of the brain, liver, spleen, heart, aorta or great

Total	548	100	469	100

arteries and veins were found in all cases, and often all these injuries were found in the same case.

5. Hanging.—Ligature was used equally by both men and women. In all but one instance, the method was hanging. Actually, the most outstanding feature of postmortem examination in these cases was the lack of pathologic lesions. Usually, only congestion of the viscera was seen and occasionally fracture of the cornu of the hyoid bone.

6. Miscellaneous.—Among the miscellaneous forms of suicide were drowning, burning and asphyxiation. Since suicide constitutes a felony*, examination should be done in every case. In all probability death by homicide, accident and natural causes has been interpreted as "suicide," and such mistakes could have been avoided in some instances if necropsy had been performed.

Homicides.—There were twenty-one homicides, less than one per year, and postmortem examination was performed in nineteen of the cases. In cases in which examination was not done, the homicides were committed prior to 1935 (one an infanticide; the other a homicide during robbery). There is no valid reason why necropsy should not be performed in every homicide and every instance of suspected homicide.

Deaths from Natural Causes

There were 1,017 deaths due to natural causes, and postmortem examination was performed in 548 of these cases. In Table III the causes of

*Minnesota statutes (Section 610.01) define a felony as "every crime which may be punished by death, or by imprisonment in the state prison or state reformatory." In Section 619.01 suicide is defined as "the intentional taking of one's own life." It is difficult to perceive, then, how successful suicide could be punished according to statutes on the basis of commission of felony, but that is a matter for the practitioners of jurisprudence to resolve.

death as entered on the death certificates are given according to organ systems.

Cardiovascular Disease.—It is noted that diseases of the cardiovascular system were the most common diagnoses made; they comprised almost the same percentage in both cases in which necropsy was done and cases in which it was not done. However, there were differences in the specific diagnoses of diseases in these two groups. For example, acute myocardial infarction was found at necropsy in 20 per cent of the deaths due to cardiovascular disease, whereas it was not diagnosed once in cases in which necropsy was not done. When postmortem examination had been done, no vague diagnosis as a cause of death was given, but when necropsy had not been done, such nebulous causes of death as "heart trouble" and angina were listed.

Central Nervous System.—The percentage of deaths attributed to lesions of the central nervous system in the cases in which necropsy was not performed also was comparable to the percentage in which necropsy was done. Cerebral vascular accident was a diagnosis much favored in cases in which necropsy was not done; it comprised 50 per cent of this group. The exact meaning of this diagnosis cannot be interpreted and, as any physician knows from past experience, it can cover a number of different pathologic processes. This diagnosis, of course, never was listed in postmortem protocols. By way of contrast, in cases in which necropsy was done 50 per cent of the deaths were found to be due to rupture of a congenital aneurysm of the circle of Willis, but this diagnosis was never made in the cases in which necropsy was not done. As mentioned above, in respect to cardiovascular causes of death, vague diagnoses also were quite common in this group when necropsy was not done. Such causes were listed as "brain trouble," "senile atrophy of the brain" and "psychiatric disorders."

Respiratory Diseases.—Five times as many deaths were attributed to diseases of the respiratory system in those cases in which necropsy was done as in those in which it was not done. It is more difficult to make a clinical diagnosis of death due to a respiratory lesion when the victim has not been under the immediate care of a physician, and this probably accounts for the marked difference. In the eighty-seven cases in which

necropsy was performed, twenty-seven persons died from pulmonary embolism, but this diagnosis was made only twice in cases in which there was no necropsy. Pneumonia accounted for approximately a third of the deaths and the remainder were due to edema of the larynx or trachea. In those cases in which necropsy was not done, more than half of the diagnoses were "pneumonia." As will be noted in Table III, "unknown cause of death" as a diagnosis was listed six times as frequently in those cases in which necropsy was not performed as in those cases in which it was done. This, we felt, was one of the most significant findings in this portion of the study.

Sudden Death.—The last analysis made was that of sudden death due to natural causes. Of the 548 cases of nonviolent death in which necropsy was done 392 (71 per cent) were classified as cases of "sudden death" (Table IV). Of the 392 persons concerned, 295 were men and ninety-seven were women. Generally, the incidences of diseases of the different organ systems were the same for males and females. Of the 392 sudden deaths 307 (80 per cent) were due to cardiovascular disease; that is, four of every five deaths. This is a higher percentage than has been reported by Janes³ (60 per cent), in England, and Helpert and Rabson⁴ (50 per cent), in Manhattan. Coronary arteriosclerosis was the most common cause of sudden death from diseases of the cardiovascular system, comprising about a half. The ratio of males to females was 4:1, slightly higher than the over-all ratio of 3:1 for all sudden cardiovascular deaths of this type. We found that this ratio of 4:1 was substantially constant for all age groups. Some authors have reported that coronary arteriosclerosis occurs earlier in males than in females, but our investigation did not bear this out. However, coronary arterial occlusion and myocardial infarction did occur earlier in the male. For example, among the males, there were eleven instances of myocardial infarction in the age group thirty to forty-nine years, and fourteen instances of coronary arterial occlusion in the age group forty to fifty-nine years, but neither of these diseases was found in the female in these same age groups. Also, myocardial infarction occurred five times as frequently and coronary arterial occlusion twelve times as frequently in men as in women. The incidence of dissecting aneurysms of the aorta, acute dilata-

TABLE IV. SUDDEN DEATH DUE TO NATURAL CAUSES

tion of the heart and hypertension was higher in the female than in the male. In this category, we also found three instances of occlusion of the coronary ostia from syphilitic aortitis and one case of blockage of the mitral valve by a ball thrombus.

Twice as many males as females died suddenly from lesions of the central nervous system. Approximately 50 per cent of these deaths were due to rupture of a cerebral aneurysm, and all of the victims were above the age of thirty years, the majority being in the sixty to sixty-nine-year age group. Of the deaths from diseases of the respiratory system, approximately two-thirds were caused by pulmonary embolism. All the victims were above the age of forty years, and were predominantly from sixty to seventy-nine years old. We found eight cases in which death was due to asphyxiation from obstruction of the air passages. These included inflammatory edema and hemorrhage from the site of a tracheotomy.

The cases of death in this group are a challenge to the coroner's pathologist, in that there is often no preceding medical history to guide him in making the diagnosis. Although a valid diagnosis cannot be made on the basis of statistics in any one specific case, a knowledge of the percentages of frequency of different categories of death is helpful.

Summary

1. A detailed review of the investigations of the coroner's office of Olmsted County from 1924 to 1953, inclusive, is presented.

2. With increasing interest in accidental and violent death and with improvement in cooperation among law enforcement officers, coroner, coroner's physicians and the state crime laboratory, more investigations have been carried out in the last five years of this study.

3. In automobile accidents, the passenger is more vulnerable to trauma to the head than is the driver, and the person who is thrown from the car is more likely to be killed than is the person not hurled from the car.

4. Trauma to the adrenal gland was seen in 13 per cent of 176 cases. The adrenal insufficiency secondary to this may result in persistent shock and, if this is true, supportive therapy will be of value.

5. Deaths caused by accidents involving automobiles and pedestrians occur in peaks at 5:00 p.m. and 8:00 p.m., whereas deaths caused by collisions of automobile with automobile occur at 6:00 p.m. and midnight.

6. Collisions of automobile with automobile resulted in trauma to the cardiovascular system more commonly than did other types of traffic fatalities.

7. Coroner's investigations of falls are of extreme importance in determining, if possible, a reason for the fall.

8. Prior to 1940 lysol and arsenic were the poisons most frequently used in suicides, but since 1940 barbiturates are the most commonly used agents.

9. There is no valid reason why necropsy should not be performed in every homicide and in every instance of suspected homicide.

10. Among the 1,017 deaths due to natural causes, postmortem examination was performed in 548. In 569 cases in which postmortem examination was not performed, the use of the term "unknown cause of death" was six times as frequent as in cases in which necropsy was done.

11. On the basis of the statistics summarized herein, other details may be adumbrated.

SURGERY TO LOOM LARGER IN PEDIATRICS

"Surgical progress in pediatrics has outstripped that of pediatrics itself in many ways, and surgery looms ever larger in pediatric practice as medical problems diminish; and diagnosis in many important surgical problems depends largely on radiological findings," Dr. John Caffey, noted New York City specialist in pediatric x-ray, has reported.

Dr. Caffey, who is associated with Babies Hospital in New York, has written a sixty-year review of pediatric x-ray in the United States. The report is part of a series commemorating the fiftieth anniversary of publishing by the *American Journal of Roentgenology, Radium Therapy and Nuclear Medicine*, in which Dr. Caffey's comments were published (September, 1956).

"It is a fact that effective pediatric surgery is untenable without accurate radiology, and pediatric radiology deserves to be a specialty more for its surgical than its medical value," the New York specialist says.

In his study of sixty years in radiology's history, Dr. Caffey traced the twin growths of pediatrics and radiology and how these two medical specialties have now fused into a sub-specialty: pediatric radiology.

"After the first burst of enthusiasm following Roentgen's discovery of x-rays, American pediatric radiology

failed to progress and actually suffered a decline, in relation to the growth of general radiology and general pediatrics, which lasted well into the 1940's," Dr. Caffey continues.

During this slow growth, the use of x-rays was extended from careful studies of skeletal maturation to present-day examinations which make possible the intricate, life-saving surgical procedures.

Dr. Caffey gives credit to the Boston Children's Hospital for the first and most important impetus given to pediatric radiology, and he quotes in his report from two physicians associated with that hospital in 1907. Their words were prophetic concerning radiology's role in medicine today.

The two pioneers, Drs. Thomas Morgan Rotch and Ariel George, said:

"As one of the primary aids to diagnosis, and also often determining the treatment for both medical and surgical cases, the Roentgen method is rapidly taking its place with all others, but in many cases proving expert physical examinations to be wrong. To diagnose and to treat without this proof (the x-ray) of correctness has in many cases proved fool-hardy, dangerous and without excuse. The Roentgen method assists, corrects and controls otherwise faulty diagnosis."

Male Hypogonadism

The Eunuchoidal Syndromes

W. E. JACOBSON, M.D.

Minneapolis, Minnesota

THE PROBLEMS associated with the study of male hypogonadism are many and to a considerable degree are rendered more difficult by the lack of entirely suitable definitions and classifications. Testicular deficiency may result in various disorders having widely different clinical and pathologic characteristics. Since the testes have a dual role, the hypogonadal diseases may reflect variable disturbances of reproductive or endocrine function. The testicular androgenic hormone is a potent anabolic substance and has among other actions a conspicuous effect upon skeletal development. Although this hormone is a growth-promoting agent, it induces epiphyseal fusion and thus causes cessation of linear growth. Androgen insufficiency during the pubertal period results in a delay in epiphyseal closure and the growth of long bones continues beyond the normal. This alteration of skeletal development results in eunuchoid proportions. Failure of testicular androgenic secretion occurring after puberty will, of course, have no effect on the established normal skeletal proportions. Thus, very prominent clinical differences will occur in the hypogonadal disorders with onset before puberty as compared with those disorders occurring initially in adulthood. With the principal exception of hypogonadism secondary to panhypopituitarism, all hypogonadal disorders with onset during or before puberty will be characterized by so-called eunuchoidal features.¹ The term eunuchoid or eunuchoidism refers to an individual who, although possessing gonadal tissue, has many characteristics similar to an individual castrated before puberty. Castration after puberty results in a eunuch but not in eunuchoidal characteristics.

The classic eunuchoidal characteristics include a high pitched voice, absence of facial hair, sparse pubic and axillary hair, infantile genitalia, small

prostate and seminal vesicles, absence of ejaculation, poor development of paranasal sinuses, poor muscular development, wrinkling of the facial skin, and a distinct alteration of the normal skeletal proportions. The eunuchoidal type of skeletal development refers to an abnormal length of the long bones. This can be evaluated clinically by a comparison of the lower body measurement (distance from sole to symphysis pubis) with the upper body measurement (distance from symphysis pubis to vertex). At birth the normal male infant has a U/L ratio of 1.69.¹ This ratio approaches 1.00 at about ten and one-half years of age and is approximately 0.98 in the normal adult male. In eunuchoidism the U/L ratio is less than 0.95. Expressed somewhat differently, the lower body measurement of a eunuchoid individual exceeds the upper body measurement by more than one inch. This disproportionate growth of the extremities can also be evaluated by comparison of the total arm span with body height. In eunuchoidal skeletal growth, the span exceeds the height by two or more inches.

Since the characteristics of eunuchoidism are usually apparent and can be evaluated by simple clinical observations and measurements, the male hypogonadal syndromes characterized by these features should be easily recognized. It is the purpose of this paper to attempt differentiation and clarification of those hypogonadal disorders in which eunuchoidism is present.

Before discussing the eunuchoidal syndromes, it would be well to briefly review the normal histology of the testis and the important pituitary-gonadal relationships. The structure of the normal testes varies considerably with the phases of normal maturation. There are six principal, although somewhat arbitrary, stages of testicular development and regression; namely, the fetal testis, the postnatal testis, the childhood testis, the pubertal testis, the adult testis and the senile testis.² Figure 1 illustrates the histologic features of the normal

Dr. Jacobson is Clinical Assistant Professor of Medicine, University of Minnesota.

From the Department of Medicine, St. Louis Park Medical Center.

adult testis. Descriptions of the normal architecture of the testis during the entire life span of the male have been presented by Albert and associates.²

Fig. 1. Photomicrograph of a normal adult testis. The seminiferous tubules are fairly uniform and are actively producing sperm. The Sertoli cells form the basal layer and the entire tubule is surrounded by the tunica propria. The Leydig cells form small clusters or islands in the interstitial spaces.

Maturation and differentiation of the testis depends to a large degree on the pituitary gonadotropins; namely, the follicle stimulating hormone (FSH) and the interstitial cell stimulating hormone (ICSH). ICSH is comparable to the luteinizing hormone (LH) of the female. Current evidence would seem to support the concept that FSH exerts its major effect upon the seminiferous tubules and ICSH causes maturation of the Leydig cells. Mature Leydig cells secrete testosterone (or some closely related androgenic hormone) which in turn tends to inhibit the secretion of the pituitary gonadotropins.

Hypogonadal disorders may result from a deficiency of the gonadotropins or as a result of primary testicular abnormalities or malformations. Theoretically, at least, determinations of FSH secretion (as reflected by urinary excretion) might be expected to offer a means of separating these two major groups of hypogonadal disorders. Present methods for determination of the urinary FSH excretion employ bio-assay techniques and have many limitations. The test is generally inaccessible, extremely costly, and of variable accuracy. A study of the histology of the testis in the hypogonadal syndromes by employing the relatively simple method of testicular biopsy offers a valuable procedure for accurate differentiation.

Deficiency of the Pituitary Gonadotropins (FSH and ICSH)

A lesion which produces total destruction of the anterior pituitary gland results in deficiency of all hormones including ACTH, somatotropin, and gonadotropins. The onset of this disorder before puberty results in dwarfism due to the more prominent effect of absent growth hormone. However, a specific and selective deficiency of the pituitary gonadotropins occurring before puberty results in a form of hypogonadism with prominent eunuchoidal features. This syndrome has been described as "Hypogonadotropic Eunuchoidism"³ and "Idiopathic Eunuchoidism with Low FSH,"⁴ Albert and associates⁵ estimate that 20 to 25 per cent of all cases of eunuchoidism are associated with this type of hypogonadism. In this syndrome, gynecomastia does not occur, pubic and axillary hair is present but sparse, and the testes are present but uniformly small. There is an absolute aspermia. Determination of the urinary excretion of 17-ketosteroids is of no particular value in the differentiation of the various eunuchoidal syndromes; however, in this disorder the excretion tends to be decreased. The urinary excretion of FSH should invariably be absent or extremely low in this form of hypogonadism. The testicular biopsy is of specific diagnostic value. The histologic structure is essentially that of a normal prepubertal testis.² Mature Leydig cells are absent and the tubules show variable degrees of maturation from lumenless cords to early tubular differentiation without spermatogenesis. The histology reveals immaturity, not atrophy (Figs. 2 and 3).

Isolated Deficiency of ICSH

Pasqualini,^{6,7} McCullagh and associates,⁸ and Landau⁹ have described cases of hypogonadism presumably due to a specific deficiency of the pituitary ICSH with normal FSH. In most instances, the deficiency apparently developed before puberty and thus eunuchoidism was a prominent clinical manifestation. Landau,⁹ however, reported an instance of this syndrome in an adult male with normal skeletal development. The syndrome has been termed "Hypoandrogenic syndrome with normal spermatogenesis"⁷ and "Eunuchoidism with spermatogenesis."⁸ The individuals have been referred to as "fertile eunuchs." Since the testicular mass depends primarily upon the presence of nor-

mal tubules, the testes in this syndrome are of normal size. Gynecomastia is apparently uncommon in this syndrome. The remaining features are common to those in other types of eunuchoidism. The

Fig. 2. Photomicrograph of testicular biopsy from case of hypogonadotropic eunuchoidism. Absent Leydig cells. Immature tubules without spermatogenesis. (R.A.: Age twenty-five. U/L ratio = 33/37. 17-KS, 3.8, 5.3, 2.8 mgs./24 hrs. FSH less than 6 mouse units.)

verified only by breast biopsy. Examination of the scrotum may falsely suggest bilateral cryptorchidism, since identifiable testicular mass may be essentially absent. The urinary 17-ketosteroid excre-

Fig. 3. Photomicrograph of testicular biopsy from case of hypogonadotropic eunuchoidism. Almost complete absence of Leydig cells. Immature tubules without spermatogenesis. Loose areolar interstitium.

(H.B.: Age twenty-one. U/L ratio = 36/38. 17-KS 14.1 and 15.9 mgs./24 hours. FSH less than 12 mouse units.)

ejaculate is essentially normal and the seminal fluid contains active normal spermatozoa. The urinary 17-ketosteroid excretion tends to be decreased, but the urinary FSH excretion is normal. Attempts at measuring the urinary ICSH by the rat prostatic phosphatase test and attempts at estimating androgen excretion by determination of the semen fructose concentration have been described, but the measurements are of questionable validity. Testicular biopsy reveals diagnostic changes in the histologic structure. There is either complete absence or marked hypoplasia of the Leydig cells. The seminiferous tubules are generally normal and active spermatogenesis is present.

Primary Failure of All Testicular Development

A primary deficiency of all testicular function may result from congenital failure of gonadal development. This abnormality, referred to as testicular agenesis, anorchia, or hyporchia, results in very severe forms of eunuchoidism. The clinical syndrome has been termed "Prepuberal non-castrated eunuchs"³ and "Functional prepuberal castrates."¹⁰ Some of the distinguishing clinical features include gynecomastia, small genitalia with marked decrease in the scrotal contents and essentially absent body hair. The gynecomastia is usually readily apparent but occasionally can be

tion is very low and the urinary FSH excretion is characteristically elevated. Biopsy of the scrotal contents reveals absence of both Leydig cells and functioning tubular structures. Derivatives of the Wolffian duct structures may be present.

Primary Failure of the Seminiferous Tubules

In 1942 Klinefelter, Reifenstein and Albright¹¹ described nine cases of hypogonadism characterized by gynecomastia, aspermatogenesis, increased FSH but without an absence of Leydig cells. Variants of this syndrome have subsequently proved to be the most common form of hypogonadism. The disorder has been described by others as "Klinefelter's Syndrome," "Puberal seminiferous tubule failure"³ and "Sclerosing tubular degeneration."⁴ The original description stressed the presence of gynecomastia; however, Heller and Nelson^{3,12,13} described cases without gynecomastia having the other characteristic manifestations and histologic features. These authors also suggested an inverse relationship between the degree of gynecomastia and the degree of eunuchoidism. Howard and associates⁴ agree that cases without gynecomastia differ in no significant way from those with gynecomastia but do not agree with any constant relationship of this sign with the other classic features of eunuchoidism. It

seems generally agreed that in this syndrome there may be varying degrees of gynecomastia and eunuchoidism. Normal skeletal development or minimal eunuchoidal proportions are common while extreme degrees of eunuchoidal skeletal proportions are less frequently encountered in this hyogonadal disorder. The scrotum and penis may be normally developed but the testes are almost always small. The ejaculate may be fairly adequate but the seminal fluid is characterized by azoospermia. The 17-ketosteroid excretion, while occasionally reduced, is most often within normal limits. The urinary FSH excretion is characteristically increased. The testicular biopsy is once again diagnostic. The characteristic histologic picture reveals varying degrees of tubular hyalinization. This is often severe with complete sclerosis of the tubule and a markedly thickened tunica propria. The Leydig cells occupy the bulk of the specimen and usually form large "adenoma-like" masses. This prominence of the interstitial cells is almost certainly due to an absolute cellular increase and not simply clumping secondary to

acteristics always indicates onset of the hormonal insufficiency prior to or during puberty. A few clinical variations may aid in the differential diagnosis. The determination of urinary 17-ketosteroid

Fig. 4. Photomicrograph of testicular biopsy from case of puberal seminiferous tubule failure. Markedly thickened tunica propria with partially hyalinized tubules. Bulk of specimen consists of large clumps of "normal appearing" Leydig cells.

(S.G.: Age thirty-two. 17-KS, 9.2 mgs./day. FSH greater than 96 but less than 196 mouse units. Normal skeletal proportions.)

TABLE I. DIFFERENTIATION OF THE EUNUCHOIDAL SYNDROMES

	Hypogonadotropic Eunuchoidism	Fertile Eunuchs	Hyporchia	Puberal Seminiferous Tubule Failure
Gynecomastia	Absent	Uncommon	Present	Variable
Testicular size	Small	Normal	Extremely small	Small
Eunuchoidal proportions	Prominent	Usually prominent	Very marked	Variable
17-Ketosteroids	Decreased	Decreased	Decreased	Decreased or normal
Urinary F.S.H.	Absent	Normal	Elevated	Elevated
Histology	Absent Leydig cells. Immature tubules. No spermatogenesis	Absent Leydig cells. Normal tubules with active spermatogenesis	Absent Leydig cells and tubules. Wolffian duct structures	Hyalinized tubules with clumps of Leydig cells

shrinkage of the tubules. Figure 4 shows the typical histologic features of this syndrome.

A highly interesting but still perplexing aspect of this syndrome has been the discovery of a "female type" of chromosomal pattern¹⁴ in the nuclei of some cells examined in patients with this hypogonadal disorder.^{15,16} However, study of the polymorphonuclear leukocytes in this syndrome has revealed a "male type" of chromosomal nuclear pattern.¹⁷

Summary

Eunuchoidism may be the outstanding clinical feature in four of the hypogonadal disorders; namely, (a) Hypogonadotropic eunuchoidism; (b) eunuchoidism with spermatogenesis; (c) primary hyporchia, and (d) puberal seminiferous tubule failure. The presence of eunuchoidal char-

acteristics of very limited value in separating these syndromes. The many limitations relative to urinary bio-assay for FSH greatly reduces the clinical application of this procedure. The use of testicular biopsy for study of the histologic features offers a relatively simple and rather clear-cut means for accurate diagnosis of the eunuchoidal syndromes (Table I).

Bonadoxin for Nausea and Vomiting of Pregnancy

JOSEPH W. GOLDSMITH, M.D., F.A.C.S.

Saint Paul, Minnesota

NAUSEA and vomiting are frequent companions of women early in pregnancy and of the surgical patient in the early postoperative period. The severity may vary from an occasional episode of mild nausea to emesis of everything consumed, solid or liquid. It may vary from day to day and from one pregnancy to another even in the same individual.

Many theories have been advanced to explain these symptoms and little agreement has been reached except that most authorities believe that they are, in part, psychosomatic. Histamine has long been blamed as one of the etiologic factors and some success in therapy has been achieved with antihistaminic drugs. Pyridoxine (Vitamin B6) has also produced some relief, as have many other drugs too numerous to mention. Consequently, it was felt that a combination of a potent antihistaminic drug (Meclizine 25 mg.)¹ and Pyridoxine (50 mg.) might prove to be an effective addition to the armamentarium of therapy.²⁻⁴ Such a combination is now available under the trade name of Bonadoxin.⁵

It is the purpose of this study to detail our experiences with the use of this drug in the treatment of nausea and vomiting. Most of the study has been in the first trimester of pregnancy, but a small additional group has been observed during the early postoperative period.

Materials and Methods

Pregnancy.—For this study, consecutive patients were taken. No attempt at selection was made with the exception that all patients were less than twelve weeks' pregnant. The composition of each group, study and control, is shown in Table I.

All of the patients were white, except for two colored multigravida in the study group and three

colored multigravida in the control group. This incidence was so low that no attempt was made to study its effect on the final results nor to separate final results into racial differences.

TABLE I. GROUP COMPOSITION

	Study Group	Control Group
Primigravida	242	237
Multigravida	378	383
Para 1	182	193
2	122	117
3	47	44
4	18	21
5	6	4
6	0	1
7	0	1
8	1	0
9	1	1
10	1	0
Total	620	620

The age distribution in both groups was essentially similar both in primigravida and in multigravida and no statistically significant age factor could be found.

Both groups were placed on a low fat, high protein diet of approximately 1500 to 1600 calories. Frequent, small feedings were encouraged (every two to three hours) rather than the usual three-meal-a-day routine of the non-pregnant woman. Adequate amounts of vitamins and minerals to satisfy minimum daily requirements were included from natural sources.

In the early weeks of this study, the control group was given no medication, but it was soon apparent that this was not a proper control since 92 per cent of these women continued to have the same or increased amounts of nausea and vomiting. None of this group were included in the study. Thereafter, all of the control group were given a colored placebo tablet composed of beta lactose. These tablets were made approximately the same size as the tablets used in the study group and were administered in the same manner (one tablet at bedtime). The results of the use of this placebo in the control group are shown in Table II.

From the Departments of Obstetrics and Gynecology, St. Joseph's Hospital, St. Paul and University of Minnesota Medical School, Minneapolis.

We are indebted to the J. B. Roerig Company for generous supplies of Bonadoxin for some of the clinical trials in these studies.

NAUSEA AND VOMITING OF PREGNANCY—GOLDSMITH

TABLE II. RESULTS WITH USE OF PLACEBO IN CONTROL GROUP

Group	Number	No Change	Slight Improvement	Moderate to Complete Improvement
Primigravida	237	53 22.4%	75 31.6%	109 46.0%
Multigravida	383	103 26.9%	97 25.3%	183 47.8%

For the purposes of this report, only complete cessation of both nausea and vomiting or elimination of vomiting and most of the nausea are considered as satisfactory results and are grouped under moderate to complete improvement. Anything less has been classified as slight improvement or no change.

In the study group, an empiric dosage of Bonadonin of one tablet at bedtime was established. The results in this group are shown in Table III.

TABLE III. RESULTS WITH USE OF BONADOXIN IN STUDY GROUP

Group	Number	No Change	Slight Improvement	Moderate to Complete Improvement
Primigravida	242	3 1.2%	26 10.7%	213 88.1%
Multigravida	378	5 1.3%	49 13.0%	324 85.7%

The average length of time therapy required to produce the above results was ten days, but in those who showed no change or only slight improvement after fourteen days, amobarbital, gr. 1/2, three times a day, was added to the Bonadonin therapy. The results of this additional medication are shown in Table IV.

TABLE IV. RESULTS WITH ADDITION OF AMOBARBITAL TO BONADOXIN THERAPY IN UNIMPROVED PATIENTS FROM STUDY GROUP

Group	Number	Unimproved	Improved
Primigravida	29	14	15
Multigravida	54	19	35

Combining the results obtained with Bonadonin alone and those in whom further improvement was obtained upon subsequent addition of amobarbital, 228, or 94.2 per cent, of the primigravida, and 359, or 95.0 per cent, of the multigravida were completely or markedly improved after therapy.

Surgery.—A small group of surgical (gynecological) patients was then studied as to the effect of Bonadonin upon the incidence of postoperative nausea and vomiting. Consecutive patients were chosen without any attempt at

selection especially as to the type of operative procedure. The composition of each of the groups, study and control, is shown in Table V.

TABLE V. GROUP COMPOSITION

	Study Group	Control Group
Abdominal:		
Total hysterectomy (with and without adnexal removal)	42	29
Salpingo-oophorectomy (unilateral or bilateral)	2	6
Ovarian cystectomy	1	3
Vaginal:		
Dilatation and curettage	27	34
Hysterectomy	1	1
Plastic repair	2	2
Total	75	75

The premedication employed in each case (both groups) consisted of pentobarbital, gr. 3, at bedtime on the night prior to surgery, and Demerol, 100 mg., with scopolamine hydrobromide, gr. 1/100, one hour prior to surgery. In the control group, a placebo tablet of lactose was given. Two tablets were administered at bedtime on the evening prior to surgery and two more tablets one hour preceding surgery. The same anesthetic agents were used in each case. In the study group, two tablets of Bonadonin were given at bedtime on the night before surgery and two more were administered one hour before surgery. Anesthetic induction was accomplished with sodium pentothal and maintenance was continued either with this agent alone or by the addition of small amounts of nitrous oxide and ether, in some of the longer procedures.

In this small series, no significant differences could be found on the incidence of postoperative nausea and vomiting from the type of procedure performed, the length of anesthesia or the actual combination of anesthetic agents used. Hence, no attempt was made to subdivide the results obtained into these subgroups but rather, each group was considered as a whole. These results in the two groups are given in Table VI.

TABLE VI. POSTOPERATIVE RESULTS WITH USE OF PLACEBO AND BONADOXIN IN INCIDENCE OF NAUSEA AND VOMITING

Group	Presence of Nausea & Vomiting	Absence of Nausea & Vomiting
Control Group	68 90.7%	7 9.3%
Study Group	5 6.7%	70 93.3%

In this study, only the complete absence of nausea and vomiting were considered as an adequate response to the therapy.

Conclusions

In a study of this nature, objective evidence of the results is very difficult to obtain and, in the pregnancy study at least, reliance must be placed on the subjective improvement reported by the individual. Admittedly, many other uncontrollable factors can enter into the results under such circumstances. However, in view of the striking differences between the control and study groups, this means of tabulating results was considered valid.

From the foregoing tables, it is apparent that Bonadoxin is a great advance in the management of nausea and vomiting both in the first trimester of pregnancy and in the early postoperative period.

Equally outstanding as the results themselves is the fact that the incidence of toxicity or intolerance to the medication was zero in the dosage employed in this study. The longest period of administration was three weeks to any one patient and the largest dose was two tablets in a twenty-four-hour period. The only side effect noted by any of the patients was moderate sedation, which was extreme in less than 5 per cent of patients taking the medication. This was usually noted within the first forty-eight hours after initia-

tion of therapy and became less pronounced by the addition of 2.5 mg. amphetamine sulfate once or twice daily without influencing the effectiveness of the Bonadoxin or producing any apparent toxicity.

Summary

1. Studies are presented to prove the efficacy of Bonadoxin in the relief of nausea and vomiting in the first trimester of pregnancy with a parallel control series.

2. Similar studies are given in a group of surgical (gynecologic) patients to demonstrate the relief of postoperative nausea and vomiting after administration of Bonadoxin preoperatively.

3. Toxicity and intolerance to the medication, in the dosage employed in these studies, was zero.

Rheumatic Fever Survey Follow-Up Study

A. B. ROSENFELD, M.D., M.P.H.
Minneapolis, Minnesota

A. C. ERLANSON, M.D.
St. Paul, Minnesota

WITH THE newer methods of prevention and treatment now available, it is important to know how widespread rheumatic fever continues to be so that modern treatment and prophylaxis may be utilized. In recent years, a growing feeling has developed among many physicians that rheumatic fever has been declining in incidence and prevalence and no longer constitutes a serious problem. During the five-year period, 1950-1954, an average of 187 cases per year has been reported to the Minnesota Department of Health. Since such reporting is known to be quite incomplete, accurate information as to the prevalence of the disease has been lacking. To obtain accurate current information, the Heart Committee of the Minnesota State Medical Association, in co-operation with the Minnesota Heart Association and the Minnesota Department of Health, undertook a state-wide survey to provide some of this data.

A simple questionnaire was mailed to the 3,063 members of the Minnesota State Medical Association, representing most of the physicians in Minnesota, whether practicing or not.¹ The questionnaires were mailed September 9, 1955, and by December 1, 50.8 per cent had been returned. Of the total of 1,519 replies, 597 doctors reported 2,297 cases of rheumatic fever during the twelve-month period (Table I). On the basis of this 50 per cent return it would appear that more than 4,000 cases were probably treated by physicians during the past year.

With the large number of cases of rheumatic fever reported in the survey in contrast to the small number of cases reported to the Minnesota Department of Health during the same period, two questions were raised by the Rheumatic Fever

Survey Committee. First, how many actual cases existed among the 2,297 reported cases? Second, how many of the actual cases met generally accepted criteria for the diagnosis of rheumatic fever? To answer these questions it was planned

TABLE I. REPORTED CASES OF ACTIVE RHEUMATIC FEVER, BY TYPE OF PRACTICE

Type of Practice	Questionnaires Returned	No. of Positive Replies	No. of Cases	Average Per Physician	Per Cent of Total Cases
Internist	173	73	258	3.5	11.2
Pediatrician	62	45	242	5.3	10.5
General prac.	707	456	1,725	3.8	75.0
Surgeon	166	12	48	4.0	2.0
Other	411	11	24	2.1	1.0
Total	1,519	597	2,297	3.8	99.7

to do a follow-up study of the reported cases of rheumatic fever by visiting a 10 per cent sample of the physicians, by type of practice, and to include a similar 10 per cent of the cases. A checklist was used for each case, which included identifying data as well as sex, age, Jones' major and minor criteria for diagnosis.² Each physician in the follow-up study was interviewed on an appointment basis by the staff pediatric consultant or a staff physician from the State Department of Health with special orientation in the rheumatic fever program. The physician's records of each case were reviewed for determination of the criteria used for the diagnosis of rheumatic fever.

The proposed sample drawn from 10 per cent of the reporting physicians of each type of practice and approximating 10 per cent of the reported cases included seven internists, five pediatricians, forty-six general practitioners, two surgeons, and two other types, from various parts of the state, a total of sixty-two physicians and 230 cases. In carrying out the study, however, it was found that several of the physicians could not be contacted because they were on vacation or out of town. Thus it was necessary to include physicians other than those originally selected. As a result, sixty-

Dr. Rosenfield is director of the Division of Special Services and Dr. Erlanson is pediatric consultant in the Section of Maternal and Child Health, Minnesota Department of Health.

This is a joint study by the Minnesota State Medical Association, the Minnesota Heart Association and the Minnesota Department of Health, with the latter carrying out the field work.

TABLE II. PHYSICIANS VISITED BY TYPE OF PRACTICE AND REPORTED AND ACTUAL CASES

	No. of Physicians	No. of Reported Cases	No. of Actual Cases	Per Cent of Actual to Reported Cases
Internist	15	35	30	86%
Pediatrician	7	68	46	68
General prac.	41	173	144	83
Surgeon	2	5	5	100
Total	65	281	225	80%

five physicians (11 per cent) were visited. These physicians had reported 281 cases of rheumatic fever representing 13 per cent of the cases in the survey. The number of physicians visited, type of practice, and reported cases is shown in Table II.

Of the 281 cases originally reported, only 225, or 80 per cent, could be separately identified as actual cases on the basis of the doctor's records or interview. Jones' criteria for the clinical diagnosis of rheumatic fever are divided into major and minor categories. The major criteria are carditis, polyarthritis, chorea, subcutaneous nodules and erythema marginatum. The minor criteria are fever, arthralgia without polyarthritis, prolonged PR interval on electrocardiogram, laboratory tests such as increased erythrocyte sedimentation rate, leukocytosis, or presence of C-reactive proteins, preceding beta-hemolytic streptococcal infection, and previous history of rheumatic fever or inactive rheumatic heart disease. To qualify under these standards a case must have two major or one major and two minor criteria.

Jones' criteria were applied to the 225 cases actually seen by the physicians. It was found that 202 cases, or 90 per cent, qualified, and twenty-three cases, or 10 per cent, did not qualify as being true cases of rheumatic fever; 116 cases, or 52 per cent, fulfilled two major criteria; eighty-six cases, or 38 per cent, had one major plus two minor criteria of Jones. The criteria of Jones by individual major and minor categories for the series of cases are tabulated in Table III.

Carditis and polyarthritis each occurred in approximately two-thirds of the cases. There were only ten cases of chorea in the series. Fever and elevated laboratory tests occurred in almost all of the cases. A history of preceding streptococcal infection was obtained in slightly over one-half of the cases. Relatively few cases were seen in which arthralgia without polyarthritis were seen. A previous history of rheumatic fever was obtained

TABLE III. JONES MAJOR AND MINOR CRITERIA APPLIED TO SERIES OF 225 CASES

	Number of Cases	Per Cent of Cases
Major criteria		
Carditis	147	65%
Polyarthritis	143	64
Chorea	22	10
Subcutaneous nodules	5	2
Erythema marginatum	11	5
Minor criteria		
Fever	212	94
Arthralgia	42	19
Prolonged PR interval (EKG)	5	2
Elevated laboratory tests	215	96
Preceding streptococcal infection	120	53
Previous history of rheumatic fever	39	17
2 Major criteria	116	52
1 Major and 2 Minor	86	38

in thirty-nine, or 17 per cent, of the cases. There were 112 females and 113 males in the series. Of the 225 cases, 152, or 68 per cent, occurred in children under the age of fifteen years.

Summary and Conclusions

A follow-up study was done on the Minnesota Rheumatic Fever Survey of 1955. This study included 11 per cent of the physicians who had reported 13 per cent of the cases in the survey. It was found by personal interviews and review of the physician's records that 80 per cent of the cases reported on the questionnaire represented actual cases of rheumatic fever. Of the actual cases, 10 per cent did not meet Jones' criteria. This study indicated that the sample of physicians studied was meeting acceptable criteria for the diagnosis of rheumatic fever in the bulk of the cases reported.

While the study answered the question as to the prevalence and incidence of the disease, as well as the diagnostic criteria used in the diagnosis of rheumatic fever, it left many questions unanswered. Among them are the number of new cases each year, age at onset of the disease, recurrences, type and effectiveness of prophylactic treatment, duration of prophylaxis, and the necessity for follow-up of cases. An epidemiologic study of rheumatic fever would be necessary to obtain these data.

On the basis of the questionnaire survey and the follow-up study it would appear that physicians probably treated about 3,000 patients with rheumatic fever in the twelve-month period, two-thirds of whom were under the age of fifteen years. This would indicate that rheumatic fever

Diagnosis and Management of Pleural Effusion

With Reference to Pleural Biopsy

W. ROBERT SCHMIDT, M.D.

Minneapolis, Minnesota

DIAGNOSIS and disposition of patients with pleural effusions at times becomes a major problem. Fortunately, pleural effusion secondary to cardiac, renal or liver disease usually can be recognized and sorted out from the other causes without difficulty, and effusions secondary to these causes will not be discussed in this paper. The pleural effusions that occur secondary to other diseases can usually be clasified under one of the following headings:

1. Effusions secondary to tuberculosis.
2. Effusions from pleural malignancies; usually the primary is in the lung or metastatic to the pleura from other foci.
3. Effusions secondary to pulmonary infarction.
4. Effusions secondary to non-specific inflammatory lesions in the lung.
5. Effusions secondary to subphrenic infections.

In most instances one can arrive at an accurate diagnosis through use of a careful history and physical examination combined with such laboratory aids as culture of the effusion, study for tumor cells, biopsy of the supraclavicular lymph nodes, x-ray evidence of the primary lesion in the lung itself, studies of the sputum for tubercle bacilli and tumor cells and finally, bronchoscopy and bronchograms.¹ Unfortunately, there are a group of cases in which the diagnosis is uncertain even after thorough investigation by the above methods, and it is in this later group that pleural biopsy obtained either through a thoracoscope or by direct thoractomy can be carried out without any great risk to the patient and will usually result in an accurate diagnosis as to the underlying etiology of the pleural effusion. In a few instances where one is certain the pleural space is obliterated, a needle biopsy may be adequate.²

It is necessary that the attending physician be accurate in the diagnosis as to the cause of a

pleural effusion since a misdiagnosis will frequently result in catastrophe to the patient. It has been very well shown that a pleural effusion secondary to tuberculosis either in the lung or in the lymph nodes will frequently clear without much treatment. Unfortunately, a high percentage of these patients, variously estimated to be somewhere between 7.5 per cent to 66.3 per cent, will develop, within a period usually of one to three years, clinical evidences of pulmonary or extrapulmonary tuberculosis unless the tuberculous nature of the effusion is recognized and the patient treated properly.³ Since many patients with a tuberculous pleural effusion show no parenchymal lesion in the lung and also since approximately 50 per cent of this type of pleural effusion will reveal no tubercle bacilli on culture or guinea pig inoculation, the tuberculous etiology, therefore, must be assumed and cannot be proven. It has been the custom to group this type of case under the heading of an idiopathic pleural effusion, and most physicians feel that all of these patients should undergo treatment for tuberculosis. Ideally, this means prolonged periods of treatment with drug therapy and with sanatorium care. With the history of an insidious onset of effusion in a young patient (below forty) coupled with a positive tuberculin test, one can be fairly certain of the tuberculous etiology. When the history is atypical and the tuberculin test negative or only faintly positive, it would seem desirable to have a more accurate diagnostic method to single out the occasional nontuberculous patient. From the few cases reported in the literature it would seem that where pleural biopsy has been utilized in the diagnosis of idiopathic pleural effusion a granulomatous type of lesion has been demonstrated.³⁻⁵ While no one has proven that the absence of a granulomatous lesion in the pleural biopsy definitely rules out tuberculosis as the etiologic factor, one cannot help but gain this impression from the reported experience.⁶ Our own limited experience

¹Presented at the annual meeting of the Northern Minnesota Medical Association, Bemidji, September 2, 1955.

with pleural biopsy tends to confirm this impression. Additional experience with pleural biopsy in the cases with idiopathic pleural effusion will shed much light on this subject.

The diagnosis of a pleural effusion due to a carcinomatosis of the pleura or other malignancies of the pleura can frequently be ascertained by presence of an obvious malignancy in the lung and by the presence of carcinomatous cells in the aspiration material obtained from the pleura. One has to be somewhat cautious, however, in the evaluation of carcinomatous cells in the pleural fluid since the pleural mesothelium can, as a result of irritation from other causes, exfoliate cells which simulate malignant cells. We have found pleural biopsy, usually obtained through a thoracoscope, to be a relatively simple and accurate method of establishing the diagnosis. While our experience in the numbers of cases is somewhat limited, we have to date established the presence or absence of carcinoma of the pleura in all instances of pleural biopsy and have had no false positives or false negatives. One cannot, however, rule out the possibility of a carcinoma of the lung from pleural biopsy since a patient may have a carcinoma of the lung with an obstructive pneumonitis and a pleural effusion secondary to the obstructive pneumonitis. In such an instance the pleural biopsy will show no evidence of carcinomatous metastasis to the pleura even though the patient does have a bronchogenic carcinoma of the lung. Fortunately, in this type of case one can usually arrive at the proper diagnosis through the use of the ordinary postero-anterior and lateral chest roentgenograms plus bronchoscopy and bronchograms.

Pleural effusions that occur secondary to small pulmonary infarcts may present very real diagnostic problems. Here there will be nothing very characteristic in examination of the pleural fluid. It may be either sanguineous or serous. The characteristic history of sudden chest pain associated with cough and raising of slightly blood tinged fluid may well be absent. The signs of phlebitis in the lower extremities such as swelling, positive Homans' sign and calf tenderness are very often absent entirely, particularly in the early phases of the disease. We have found that the clinician must entertain a high degree of suspicion and constantly keep in mind the possibilities of pleural effusion secondary to recurring small emboli in order to arrive at the proper diagnosis. The diagnosis is frequently one of

exclusion. One frequently is alerted to the possibility of a pulmonary embolism by such factors as bilateral involvement, the rapid appearance of new areas of infiltrate in the lung, sudden episodes of rapid pulse and dyspnea out of proportion to the visible changes in the lung, and finally by the satisfactory response to anticoagulant therapy. Since recurring pulmonary embolism even in younger individuals may prove fatal unless the condition is promptly recognized and properly treated, it is essential that this disease should always be considered when seeing a patient with pleural effusion not explained on other grounds.

Pleural effusions secondary to nonspecific pulmonary infections have become somewhat uncommon as compared to the pre-antibiotic era when empyema occurred not infrequently following a pneumonia. Today, the type of effusion that is seen following nonspecific inflammation of the lung may represent a challenging diagnostic problem, since very often the pneumonitis which has been the source of the effusion has been treated with antibiotics so promptly that it escapes detection and is, therefore, unrecognized as the source of the pleural effusion. In these cases a careful history may lead to the proper diagnosis, inasmuch as a rule these patients start out with an acute illness with a high fever and possibly a shaking chill. When an onset of illness of this type is followed immediately by the use of wide spectrum antibiotics, one is usually correct in assuming the pleural effusion represents an attenuated type of empyema. The bacteria present in these effusions may be so attenuated that they fail to grow on culture. The lysins normally produced by the bacteria present in an empyema will be reduced and for this reason a marked deposition of fibrin on the collapsed lung will occur in these attenuated empyemas. This deposition of fibrin over the collapsed lung and within the substance of the effusion itself interferes with the usual methods of drainage of the empyema and obliteration of the pleural space. Consequently, decortication of the lung and obliteration of the pleural space by use of open thoracotomy must be resorted to before these patients can be considered cured. We have seen a number of these patients treated with antibiotics alone. They appear to remain well as long as the antibiotics are continued; however, several weeks after discontinuing the antimicrobial therapy the patient again becomes slightly febrile and shows the usual signs of chron-

ic low grade empyema. These patients will remain chronically ill until the slightly infected pleural pocket is obliterated by appropriate surgery. When one sees these patients a number of months after their original infection, it is not surprising that the proper diagnosis might be confused with such conditions as tuberculous pleural effusion and carcinoma with pleural effusion. Here biopsy of the pleura will not only establish the proper diagnosis but, since it can be combined with decortication, will result in cure of the patient.

The following case history is an illustration of a patient with an effusion from an attenuated empyema.

Case Report

M. G., a fifty-four-year-old woman was admitted to Doctors Memorial Hospital March 3, 1955, with the following history. In January, 1955, she developed sudden pain in the left lower chest associated with fever. She was treated at home with several different types of antibiotics by mouth. She shortly became afebrile and appeared to recover. Four weeks later she was admitted to a hospital because of pleural effusion and at that time 1,500 cubic centimeters of fluid were aspirated from the left chest. Towards the end of February she noted dyspnea on exertion, and investigation at that time again revealed a recurrence of the left pleural effusion. On her admission to the hospital in March, the laboratory studies showed a hemoglobin of 14.5 grams, a white blood count of 7,950, and an elevated sedimentation rate of 36 millimeters in one hour. Twelve hundred cubic centimeters of slightly bloody fluid were removed from the left chest. The Papanicolaou stains showed atypical cells which were thought to be neoplastic in origin. Daily aspirations of about 1000 cubic centimeters of bloody fluid were done on her second and third hospital days. Investigation of the thyroid, breasts, kidneys, gastrointestinal tract and pelvic organs revealed no evidence to suggest a primary lesion with pleural metastasis. In addition, there was no evidence of a primary carcinoma in the lung. The patient was discharged March 9, the feeling at that time being that she had a neoplastic process of the pleura with the primary site undetermined. On March 16 she was seen in the office of her physician, and 1200 cubic centimeters of bloody fluid again aspirated. She was readmitted to the hospital March 20, 1955, for further investigation. The gross appearance of the pleura and the biopsies of the pleura revealed no carcinoma of granulomatous lesion. It was decided at this time that the patient had an attenuated empyema following a pneumonia in January, which had been treated and aborted with antibiotics. Consequently, on March 28, a decortication of the left lung was carried out. Bronchoscopy was done just prior to the decortication; this was entirely negative. The gross appearance of the pleura at this time was consistent with that of a

chronic fibrin thorax following an attenuated empyema. The entire left lung was collapsed and bound down by a fibrous peel against the mediastinum. The lingula of the left upper lobe was also contracted beneath the fibrous membrane. The lung decorticated with some difficulty; however, after decortication it expanded readily. There was no palpable disease in the underlying lung. The patient has had an uneventful convalescence. Cultures of the pleural material obtained at operation have been negative for acid fast bacilli. The microscopic study of the pleura showed no evidence of tuberculosis or carcinoma. The microscopic diagnosis was a chronic fibrinous pleuritis. She was discharged from the hospital on her eleventh postoperative day and has been well.

In a small series of pleural biopsies done in the case of patients in which the conventional methods of diagnosis did not lead to a definitive diagnosis, the results are as follows:

RESULTS OF PLEURAL BIOPSY

Patient	Preoperative Diagnosis	Postoperative Diagnosis
1. E. S.	_____?	Mesothelioma
2. W. H.	Carcinoma?	Fibrous Pleuritis
3. M. B.	Tuberculosis?	Fibrous Pleuritis
4. M. G.	Carcinoma?	Attenuated Empyema
5. Z. B.	Carcinoma?	Carcinoma

Summary

The etiology and treatment of pleural effusion secondary to disease of the lung or pleura may at times be impossible, utilizing the conventional diagnostic methods. The common causes of pleural effusion are those secondary to tuberculosis, those secondary to metastatic carcinoma in the pleura, effusions secondary to pulmonary infarction and effusions secondary to nonspecific inflammatory lesions in the lung. The results of an improper diagnosis may be disastrous for the patient. It is suggested that in the occasional patient where conventional diagnostic methods fail to prove the diagnosis, pleural biopsy be done in an effort to establish a more accurate clinical diagnosis. Pleural biopsy is a procedure which is not hazardous to the patient and a procedure that will enable the clinician to arrive at an accurate diagnosis. The results of a small series of pleural biopsies are summarized.

Case Presentation

Acute Emphysematous Cholecystitis

JOHN F. ALDEN, M.D.
S. HARTLEY CALIN, M.D.
JOSEPH L. SPRAFKA, M.D.

Saint Paul, Minnesota

SINCE Hegner¹ recognized emphysematous cholecystitis roentgenographically in 1931, the total number of cases reported has reached fifty-two.² Previously the entity had been recognized only at autopsy or laparotomy. The disease, also known as acute pneumocholecystitis, consists of the presence of gas in the gall bladder, often associated with an interstitial emphysema of the gall-bladder wall. The source is probably anaerobic gas forming organisms which have been harbored in the liver and which are normally nonpathogenic. These are likely secondary invaders which complicate the picture of acute cholecystitis by the formation of gas in and about the gall bladder.³ The disease is more common in male subjects and is often associated with diabetes mellitus. Gallstones are usually present.

The location of the gas in the gall-bladder wall is submucous, as has been shown by gross and microscopic examination of specimens.⁴ However, gas may extend into the pericholecystic tissues in more extensive infections. This explains the characteristic roentgenographic findings which consist of an intraluminal air fluid level surrounded by a halo of lesser density representing gas within the gall-bladder wall. The biliary tree is not outlined by air as in instances of biliary fistulae.

Since emphysematous cholecystitis is associated with an increased incidence of gangrene of the gall bladder and an increased mortality, early cholecystectomy appears to be the treatment of choice.³

Case Report

History.—A sixty-eight-year-old alcoholic, unmarried white laborer of Polish extraction was admitted to Ancker Hospital, December 5, 1955. He complained of abdominal pain, tenderness and distention of four days' duration, and stated that this had been preceded

for ten days by pain in the right flank which radiated to the abdomen. He had vomited several times and thought that the vomitus had been bloody and his urine darker than normal. Shortness of breath and nocturnal dyspnea had been present for two weeks. For several years, he had had urinary frequency, dysuria, urgency, and nocturia. He had no previous dietary difficulties or abdominal distress.

Physical Examination.—On examination the temperature was 102° F, pulse rate 100 per minute, respiration 40 per minute, and blood pressure 105/70.

The patient was obese, confused, orthopneic and complained of abdominal pain. He was slightly cyanotic and had minimal icterus. The heart was totally irregular but no murmurs were audible. A few moist rales were present at the bases of both lungs. His abdomen was distended and tympanitic. A smooth tender mass could be felt extending six centimeters beneath the right costal margin. The entire abdomen was tender and there was rebound tenderness referred to the right upper quadrant. The bowel sounds were normal. Aside from moderate prostatic enlargement rectal examination was normal.

Laboratory Findings.—The hemogram was normal except for a moderate polymorphonuclear leukocytosis. The urine contained albumin, casts, and occasional erythrocytes and leukocytes but no sugar. The serum bilirubin totaled 4.0 mgm. per cent, of which 3.2 mgm. per cent was determined by the direct reaction. The cephalin flocculation was 2 plus in twenty-four hours.

The electrocardiogram showed auricular fibrillation.

Roentgenographic Findings.—Roentgenograms of the abdomen revealed an area of radiolucency in the right upper quadrant which corresponded in size, shape, and position to the gall bladder. This was surrounded by a ring of decreased density (Fig. 1). An air fluid level was present within the shadow. Roentgenographically the diagnosis was acute emphysematous cholecystitis. There was minimal small bowel gas and some gas within the colon (Fig. 2). No free intraperitoneal air was evident. A roentgenogram of the chest showed moderate cardiac enlargement and congestion of the lungs.

Course in the Hospital.—The patient was digitalized and placed on large doses of antibiotics. Combined

From the Departments of Surgery and Radiology, Ancker Hospital, Saint Paul, Minnesota.

tentanus-gas gangrene antitoxin in therapeutic amounts was administered.

At 5 p.m., December 6, 1955, under general anesthesia, the patient was explored through a right sub-

costal incision. The gall bladder was found to be tense, thin walled, partially gangrenous, and walled off by adherent omentum and adjacent viscera. When the adherent omentum and transverse colon were freed from the gall bladder, free bile was encountered. Aspiration of the gall bladder revealed that it contained 40 cc. of gas. A cholecystectomy was done. The region of the common duct was examined but no dilation or stones were found. Because of the patient's poor condition and the severe infection and reaction in the tissues about the cystic and common duct, a common bile duct exploration was not done. The wound was closed with drainage of Morison's pouch. The night of the operation the patient pulled out the Penrose drain but nevertheless ran a benign course, his highest temperature being 101.2 degrees rectally on the third postoperative day. His serum bilirubin promptly reverted to normal. Later studies provided evidence of minimal diabetes mellitus.

Pathologic examination of the gall bladder revealed it to be gangrenous. The mucosa was raised from the

submucosa and a dense polymorphonuclear leukocytic invasion of the wall was present. No stones were found in the specimen and none were encountered during the operation. Aerobic cultures of the gall-bladder contents showed no growth. Anaerobic studies, unfortunately, were not done.

Summary

The fifty-third case of acute emphysematous cholecystitis has been presented. A brief discussion of the characteristic features of the disease is included.

(Continued from Page 103)

continues to be a prevalent disease and constitutes a serious problem in Minnesota. Physicians and the public should be aware of the importance of early diagnosis, the availability of effective treatment and the necessity for long-term prophylaxis.

Continuation Study

Abdominal Injuries

DANIEL J. MOOS, M.D.

Minneapolis, Minnesota

ETYMOLOGIC consideration of the word *abdomen* indicates that *hidden* may well be its meaning. The anatomic structures which are so hidden are peculiarly liable to injury from closed or open wounds, and the effects of such injury are particularly lethal. Therefore, constant thought of the danger which is *hidden* and the employment of tactics designed to extract from this place of concealment pertinent diagnostic facts early enough to allow timely treatment are the absolute prerequisites for successful management of trauma in this area we call the abdomen.

Of first consideration when clarifying concepts of the problem of trauma is the matter of attention to the wounded person where he or she may initially be found. Almost always this attention is conducted by lay individuals of varying experience. To those who may receive instruction from us in such matters, e.g., ambulance drivers, litter bearers, police, first aid students, et cetera (a group of people who are greatly increasing in number commensurate with civilian defense activity) succinct instructions are in order. In this discussion, general principles of transportation and resuscitation are omitted and mention made only of factors relative to the abdominal injury itself. The noneviscerating abdominal wound should simply be covered with a sterile or clean, small dressing. When evisceration has occurred, no attempt at gut replacement is in order at this time. A sterile or clean voluminous dressing over the exposed viscera, held in place by a firm bandage encircling the trunk, is practical and of value. Only when protracted (days) exposure is likely should moist dressings be considered, and even then their value is dubious. Transportation to an effective center for definitive treatment by the most rapid and direct method available is indicated. Any theoretic danger of removal via air based on relationship of atmospheric pressure to intraluminal visceral pressure is far outweighed

by the material advantages gained through the rapidity of transportation which allows early surgical repair with its attendant benefits. Once applied, dressings should remain in place until they can be removed by the surgeon responsible for care of the injury. Each dressing change in these wounds, as in others, affords another opportunity for bacterial contamination and usually serves no useful purpose. Administration of morphine at the time of injury may be of value. If given, it must be noted unmistakably on a record attached to the patient.

Upon arrival at a hospital, a history of the accident together with a brief pertinent examination furnishes the basis for assessing the problem at hand. Simultaneously, resuscitative measures may be begun in the emergency room and on the way to the hospital bed. A scout x-ray film of the abdomen should be taken. Crossmatching for blood transfusion and obtaining a blood sample for hemoglobin and hematocrit values form another essential part of this workup which is best started immediately in the emergency room. Time is important. Mortality is often directly related to time elapsed between injury and treatment. We have repeatedly found that the baseline established rapidly by prompt history, physical examination, scout film of the abdomen, urinalysis, hemoglobin and hematocrit determination is invaluable.

With the foregoing general considerations in mind more specific discussion of the problem at hand is in order. Classification is simple and further subdivision than open and closed wounds is unnecessary.

Closed Abdominal Wounds

Many of these injuries will obviously be trivial and need no further attention. We are concerned in this discussion with those of serious potential or actual degree. The abdominal wall suffers a contused wound with or without partial or complete division of muscular or connective tissue

Presented at the Center for Continuation Study, University of Minnesota, January 31, 1956.

components. Hemorrhage there can occur from the intracutaneous position to the immediately extraperitoneal. Any intra-abdominal structure may be injured. Damage to hollow viscera may occur more frequently at their points of fixation. Damage is often secondary to skeletal injury from pelvic or rib fractures. The true appreciation of the word *hidden* can be well understood by him who surveys the injured abdomen of this type. One's duty, however, is remarkably clear. Unless he is prepared to prove unequivocally that no visceral damage has occurred, hourly or more frequent clinical, laboratory and x-ray examination must be done until the sixth post-injury hour. If after this period of time any symptoms or signs of peritoneal irritation, with or without evidence of intra-abdominal hemorrhage remain, surgical exploration of that abdomen is indicated. This rule may seem unnecessarily harsh and leave little room for the so-called conservative treatment of these injuries. If one waits for evidence of exsanguinating intra-abdominal hemorrhage or far advanced inflammatory changes throughout the peritoneal cavity, he is fortunate indeed if mortality can be avoided. Antibiotic drugs and blood transfusions are no substitute for closure of a hole in the gut by suture, or ligation of a bleeding artery. Again, I must emphasize that we are dealing with something which is *hidden* and the signs apparent to us especially in the early period may be slight indeed. What are these signs and symptoms—how are they elicited, interpreted and judged? Persistent abdominal pain with tenderness to palpation, especially if associated with some degree of muscle spasm and rebound tenderness, is the first warning sign along the way. Evaluation of tenderness and muscle spasm may be difficult relative to true location and degree. A nervous, apprehensive, recently injured patient often is not a good subject for precise evaluation of these findings. If one will prepare one quarter grain of morphine in 10 cubic centimeters of water and administer it fractionally over a period of five minutes by the intravenous route, discontinuing injection at the moment that the patient obviously begins to relax, valuable information may be secured.¹ Slight and irrelevant degrees of abdominal tenderness disappear and along with this much of the voluntary muscle spasm. Muscular rigidity and some degree of tenderness now tend to become sharply localized over the area of pathology. If such abdominal

findings remain after this degree of analgesia, serious import must be attached thereto. It must be realized that this procedure should be done by the surgeon who is to accept final responsibility for the case at hand and he should examine the patient before and after morphinization. It is often wise when such localization has been secured to prepare the skin of the abdomen and insert with the aid of local anesthesia a short beveled needle into the peritoneal cavity and aspirate its contents. If one obtains blood, recognizable intestinal content, bile or dye previously ingested into the stomach, the information secured is indeed valuable. The use of a needle large enough to admit a polythene tube which may be inserted deep into the abdomen thereby reaching more areas has been suggested. In view of the great difficulty of adequately sterilizing such tubing, we do not recommend its use for this purpose at present. Pain referred to the shoulder strap area is suggestive of diaphragmatic irritation. It may occur on the left when the spleen is ruptured (Kehr's sign). Vomiting often occurs at the time of injury and usually does not recur until late. Abdominal distention is likewise a late sign and should not be awaited. Shifting dullness in the flanks due to the accumulation of blood in the peritoneal cavity is not a sign amenable to easy interpretation in acute injuries. The appearance of blood in the rectum or urethra is pathognomonic of injury in the lower reaches of the bowel or somewhere in the genitourinary tract. Discussion of these injuries in detail does not fall within the scope of this paper. Suffice it to say that such occurrence must be immediately investigated. At times, rapid early tumefaction localized to one or another portion of the abdominal wall may be seen. This is usually indicative of a hematoma forming there. Careful physical examination of the chest should never be omitted. When, following injury to the upper abdomen or chest, the cardiac dullness shifts to the right, breath sounds disappear on the left and dullness or tympany are noted in the left chest, the possibility of traumatic diaphragmatic hernia must always be considered. Rarely a diaphragmatic tear occurs on the right. Unrecognized strangulation of these herniae is associated with an extremely high mortality.

Classic signs of hemorrhage, i.e., air hunger, pallor, low blood pressure, and a thready, rapid pulse, may be associated early with attendant

hemoconcentration effectually masking common laboratory findings indicative of anemia. Volumetric red blood cell mass and plasma determinations do clarify this problem and may be used advantageously to estimate the degree of hemorrhage and necessary blood replacement volumes. If intra-abdominal hemorrhage is slow or intermittent, as is often the case, falling hematocrit and hemoglobin values are diagnostic.

X-ray examination of the abdomen in the lateral decubitus, flat and upright positions is often very helpful. One must remember to examine the films in a slow methodical manner thinking of each organ, system and structure singly. It is valuable to develop a routine method of doing this in order to avoid missing obvious findings. Free gas demonstrable under the diaphragm or under the parietal peritoneum in the lateral decubitus position is positive proof of a ruptured hollow viscus. It is an early sign in a high percentage of stomach and colon injuries. It occurs somewhat later in small bowel lacerations. Tears of the retroperitoneal portions of the duodenum are manifested by gaseous shadows along the psoas border, occasionally outlining a kidney or often appearing as multiple longitudinal streaks in the duodenal area. Splenic tears with masses of softly clotted blood accumulating in the left subdiaphragmatic region may displace the stomach gas bubble medially and inferiorly. At times an increase of density suggesting a mass will be seen in the left upper quadrant. Fractures of the lower ribs on either side are significant, for one may puncture the liver or spleen. Esophageal tears may be manifested by streaking of gas longitudinally in the mediastinum. Elevation or irregularity of a diaphragm is generally the first clue to a diaphragmatic hernia. Hemorrhage from a torn kidney may obscure the renal shadow or psoas margin or both. Fractures of the pelvis automatically bring to mind the possibility of bladder or urethral injury. Cystograms furnish a safe, simple confirmatory procedure in this instance. Intravenous pyelography will usually demonstrate renal lacerations. It should be remembered that sacral fractures may be associated with injuries to the pelvic colon at its point of relative fixation. Fractures of the vertebrae with their rather regularly attendant ileus because of retroperitoneal hemorrhage frequently explain the presence of abdominal distention. The presence of radiopaque foreign bodies is usually obvious

and often of value in ascertaining the likelihood of injury to one or another structure. Usually the administration of contrast material by mouth or rectum is unnecessary and may be dangerous at times. However, a small amount of diodrast will be helpful especially in lower esophageal tears.

When these clinical, laboratory and roentgenologic features are classic, the diagnosis and proper therapeutic procedures are clear cut. The difficulty lies in making the proper diagnosis before the findings are obvious. A high index of suspicion with a thorough knowledge of the implications of suggestive findings is necessary. Surgical exploration at this time pays great dividends. If the ruptured spleen is removed at the first moment in which one begins to think of it as a possibility, far more pleasant surgical experiences will be accumulated and fewer surgical adventures will occur. The structures involved are *hidden* and in the last analysis any sound, though slight, evidence of damage must be thoroughly investigated.

Treatment of closed abdominal injuries resolves itself into two aspects, i.e., the necessity for systemic treatment and the necessity for local therapy to the abdomen and its hidden contents. The alleviation of pain, apprehension and restlessness by morphine is universally acknowledged. Yet one must never narcotize an individual carelessly to a point where real symptoms are masked. Morphine ordered freely to be given at the discretion of the nursing staff has stifled many an outcry which, if brought to the surgeon's attention, would have enabled him to recognize serious symptoms. These drugs should be used intelligently and only in doses which do not further *hide* the already *hidden*. When shock is present, the treatment of choice is whole blood administered intravenously. Plasma and artificial plasma expanders are useful as interim agents. It is almost always a mistake to operate upon an individual in shock. Resuscitative measures, which in the main consist of whole blood administered rapidly by one or more routes, will restore blood volume to a point where anesthesia and operative intervention can be safely undertaken. If the patient survives long enough to come to the surgeon's care, bleeding will have been slow enough or sufficiently arrested to allow preoperative restoration of a large measure of his blood volume. The others will have died of exsanguination beforehand. At this point vasopressor drugs are of no

value and may be harmful. If one has reason to suspect intraperitoneal bacterial contamination, penicillin and dihydrostreptomycin should be administered as soon as possible and are the antibiotic drugs of choice unless objective evidence is secured that another will be more effective. One never treats an abdominal injury solely with these agents—they are only an adjunct to the well-defined principles of operative therapy shortly to be discussed. Preoperative medication of atropine or related substances and morphine are well standardized. It is well to remember that in the injured patient subcutaneous or intramuscular administration of drugs may be attended by slow or irregular absorption. For this reason, intravenous administration is advantageous. Preoperative emptying of the stomach is imperative. For lack of it, individuals have drowned in their own stomach contents when vomiting occurs during induction of anesthesia. The most practical way to empty the stomach in emergency cases is to induce vomiting in the conscious patient. Do not rely on the use of a tube—a sense of false security may ensue with disastrous consequences to the patient. An indwelling intragastric tube attached to suction is helpful during anesthesia in keeping the stomach empty. Gas, especially, may be forced down the esophagus by the anesthetist's efforts to assist respiration, and gastric dilation ensues, making the operative procedure far more difficult. Insertion of a nasal tube can of course be done then, but it is harder and more time consuming.

The choice of anesthesia in the last analysis rests on that agent or agents with which the surgeon and anesthetist are most familiar and can use to best advantage. For an anesthetist, who 98 per cent of the time employs a nitrous oxide-ether inhalation technique, suddenly to switch to cyclopropane because he is dealing with an injured individual is foolhardy and dangerous. If the anesthetist will maintain a clear airway at all times, ventilate the patient properly in an effort to avoid respiratory acidosis, and supply the surgeon with a reasonable degree of anesthesia fitted to the procedure at hand, it probably makes little difference what anesthetic agent is used. Rapport must exist between surgeon and anesthetist to make sure that they operate as a team and not each go a separate therapeutic way. If unnecessary depth of anesthesia is avoided and adequate ventilation maintained through a patent

airway, critically injured patients may be anesthetized with safety. In the absence of skilled specialists in anesthesiology, highly potent agents such as cyclopropane are best avoided unless the administrator thereof is practiced and competent with them through daily familiarity. If diaphragmatic lacerations complicate abdominal injury, remember that the surgically opened abdomen then communicates with the chest, and controlled respiration, preferably through an intratracheal tube, is necessary. It is well also to recall that direct infiltration of novocaine into the abdominal wall, peritoneum or splanchnic region affords an admirable adjunct to general anesthesia at a light plane. Supportive therapy during surgery in the way of blood transfusion may be necessary. An intelligent effort to estimate the blood loss by weighing sponges and measuring losses in suction bottles should be made. Correlation of this with preoperative estimates based on the amount of blood already given, hemoglobin and hematocrit values and preferably quantitative blood volume determinations should be made. Transfusion should not be for psychic comfort to the surgeon or anesthetist but for the replacement of actual blood lost. The dangers of overtransfusion are real and the detection of incompatibilities of the blood administered may be heavily masked by anesthesia. Recently we have found that actual determination of red blood cell mass and plasma volume while surgery was in progress was not difficult or cumbersome, and afford a reliable measurement of the exact situation (Evans blue dye method). Similarly one should avoid overloading of the body with water and salt. Trauma elicits endocrine and mechanical responses which tend to conserve these substances. Therefore, large quantities of either need not and should not be given during acute phases of injury unless objective evidence indicating their need exists.

If an exact preoperative diagnosis can be made, an incision designed adequately to expose that region should be used. Long muscle splitting right rectus incisions are poor companions for surgeon and patient. They have the greatest tendency to dehiscence, are more painful with attendant ipsilateral thoracic splinting, and contribute more frequently to postoperative herniae than any others. Well-executed transverse or longitudinal midline incisions which may be combined if need be are far more suited to the

patient's needs. In the absence of precise knowledge concerning the organ involved, a good guide to incision is the point of maximum tenderness or spasm. At times it may be necessary to extend incisions into the chest with or without dividing the diaphragm or resecting a rib. Thoraco-abdominal wounds in particular may call for this. Removal of blood, debris and devitalized tissue, together with hemostasis in the chest cavity, obviate the necessity later for many pulmonary decortications and prevent development of stubborn empyemata. Catheter drainage of the chest with slight negative pressure (8 centimeters of water) or underwater seal is usually advisable following this procedure.

When the peritoneal cavity is opened, immediate observation of its contents is important. The presence of gas, bile, blood or feces and the presence or absence of serosal inflammation, together with the character of the exudate, often furnish an immediate guide to the source of trouble. Sites of injury identified should be tagged in the case of perforated gut with suitable clamps which mark the injury and temporarily close the perforation to prevent further contamination. The source of active hemorrhage should immediately be located and dealt with. Painsstaking examination of the gut from esophagus to anus should then be carried out. Missed perforations are a common cause of death. Injury to retroperitoneal areas should be thought of and searched for. The stomach must be examined in front and in back. If necessary, the gastrocolic ligament must be divided and the lesser sac explored. The pancreas, spleen, liver, gall bladder and bile ducts, together with the duodenum, are looked at carefully. If one suspects a duodenal tear in the retroperitoneal portion, mobilization of the colon should be carried out so that the duodenum may be exposed, examined and repaired if necessary. A ruptured spleen necessitates splenectomy. Lacerations of the liver are closed by deep mattress sutures after any devitalized tissue has been removed. Ligation of large vessels and ducts within the liver substance is practical and greatly aids hemostasis and biliary stasis. Placement of a soft Penrose drain around the hepatic pedicle, so that the hepatic artery and portal vein may be intermittently occluded, is at times of great value in controlling blood flow from the torn liver surfaces. Placing a gelfoam pad between the torn surfaces as an adjunct to suture is of help. Adequate

drainage of liver injuries is necessary for often much bile leakage occurs. A ruptured gall bladder should be removed. Common bile duct injuries usually are associated with retroperitoneal infiltration of bile especially in the region of the gastrohepatic ligament. This makes location of the site of injury difficult. If it can be found, careful repair should be done, supplemented by T-tube duct drainage. If the tear cannot be found, T-tube drainage alone must suffice. Pancreatic injuries necessitate hemostasis, excision of dead tissue, repair if possible, and adequate drainage. This may be of value in preventing subsequent cyst formation. Mesenteric hematomata are ordinarily allowed to remain undisturbed provided they are not unduly large or associated with obvious active bleeding or definite circulatory embarrassment of the bowel. Small lacerations of the bowel are best closed in two layers with special attention being given to preventing constriction of the bowel lumen. If lacerations are extensive in degree or numerous in an isolated area, resection of the damaged segment with immediate end-to-end anastomosis is preferable. There are virtually no circumstances which justify exteriorization of small bowel with the thought of later restoration of continuity. If resection and anastomosis are indicated they should be done immediately and the bowel replaced in the peritoneal cavity. Injuries of the colon must be carefully assessed on the basis of degree of damage, extent of peritoneal contamination and circulatory status of the gut wall. Colon injuries which are any more than puncture wounds, especially if associated with extensive peritoneal contamination or additional damage to other structures, should be exteriorized and handled as any temporary colostomy. If resection of a portion of the colon is found necessary, primary anastomosis is not indicated. The two limbs of the bowel should be brought out as a double-barreled colostomy, perhaps using a Rankin clamp. When anatomic location renders exteriorization unfeasible, as for example low in the pelvic colon, proximal colostomy must be done unhesitatingly if there is any doubt about the closure from the standpoints mentioned previously. We must not be misled by the sense of security established by continued experience with the prepared empty colon found in the elective surgical case. Acute injuries to the unprepared bowel are dangerous and must be handled circumspectly. It is in this

type of problem that antibiotic therapy does much to lessen the threat of sepsis from peritonitis or wound infection.

Drainage of the peritoneal cavity is a moot point. It is our feeling that, if a hole in the gut wall cannot be closed or if the closure be precarious, one or two Penrose drains from that site to the outside are of value. If the pancreas or liver are injured, copious quantities of bile or pancreatic juice may exude and should have the aid of established external drainage. Expecting the entire peritoneal cavity to be drained for the treatment or prevention of generalized peritonitis through one or more rubber drains is foolish. If tissue that is actually or questionably devitalized must be allowed to remain in the belly, external drainage of the area may be of benefit. The thought of draining the abdominal wound, especially if it is heavily contaminated, has merit and may occasionally prevent abscess formation under tension. The history of abdominal surgery is replete with description of the use of chemical or biologic agents placed in the peritoneal cavity to prevent or treat infection, diminish adhesion formation or promote healing of anastomotic sites. None have stood the test of time and many have proven to be dangerous. Hope is eternal in the surgeon's breast and at present the thought of placing several small polythene tubes in different areas through small puncture wounds in the abdominal wall made before closure for the purpose of instillation of antibiotic agents is being considered. Sterilization of polythene tubes is still a major problem accomplished best at present by high intensity beta or gamma radiation. Careful closure of the operative incision so that large amounts of foreign material, and dead space to allow collection of serum and blood, do not remain is important. Careful hemostasis with absence of tissue devitalized by ligature, suture or cautery promotes kindly healing. The wound closure too must have sufficient strength. There is much to be said for a one layer through and through suture closure in any abdominal incision in which postoperative complications are likely.

Postoperative care varies with the type and extent of injury. Early mobilization of the patient is advocated and practical. If fractures or other associated injuries prevent this, a routine of bed exercises should be employed. Remember that patients may be effectually immobilized by means of morphine or related drugs. These must be used

sparingly and for a short period of time only, if complications due to circulatory, respiratory or musculoskeletal stasis are to be avoided. If a valid reason exists for antibiotic therapy, it should be employed. Tetanus toxoid as a booster injection is indicated in the immune and antitoxin in large doses in the unimmunized individual. Gas gangrene antiserum is of questionable value and is followed by many severe allergic reactions. Decompression of the gastrointestinal tract through indwelling catheters for a short period postoperatively does combat abdominal distention especially in individuals who tend to swallow air. One must constantly remember that its prolonged use is dangerous. Even though the loss of water and electrolytes from the body which it causes can be calculated by nice mathematical formulae and exactly replaced, it is far better to produce no such deficits in the first place by allowing oral ingestion of food and water at the earliest possible date. With this principle in mind, each case will present individual requirements and the bounds of safety will not be overstepped. Blood transfusion is usually not necessary during this time unless continued blood loss should occur. Management of drains and general wound care differ only from elective surgical cases in that the likelihood of bacterial contamination is great if the gut has been perforated. Therefore, signs of sepsis should be searched for frequently and dealt with as and if the occasion arises. Concomitant injuries should be treated in the order of their priority. If early and proper resuscitative, diagnostic and therapeutic procedures are followed, the postoperative course should not differ greatly in manner from elective abdominal operations.

Open Abdominal Wounds

The nature of the physical agent producing the open abdominal wound is of considerable importance. Small pointed objects, such as the ice pick, produce injuries which differ greatly from those inflicted by the large jagged shell fragment. High velocity (2000 to 2800 feet per second), small caliber (30 or less) hard nose bullets at near to medium range more nearly resemble the ice pick injury than does the low velocity (1000 to 1500 feet per second), large caliber (45 or over) projectile at shorter ranges. The devastation produced by a shotgun blast at close range is a definitely different diagnostic, therapeutic and potentially lethal problem than a single puncture from a .22

caliber rifle. Certain small caliber super velocity rifles (3000 to 4000 feet per second) often tend to produce explosive effects on striking flesh due to disintegration of the projectile on impact. So, in approaching the problem of outlining our plan for management of open abdominal wounds, the exact nature of the wound itself is of prime importance. While it might be perfectly proper to remove and replace a colon which presented two small puncture wounds, similar procedure with a badly lacerated bowel and mesentery could well lead to disaster.

Much of what has been said previously in regard to closed injuries also applies to open abdominal wounds. They differ only in that the indication for surgical exploration of the abdomen is far more clearcut and that one has the additional problem of managing the wound of the abdominal wall. It is safe to say, and has been said many times before, that, unless definite proof exists showing that penetration of the peritoneal cavity did not occur, all such abdomens must be surgically explored. The wounds of entrance and exit are handled as other contaminated wounds. They are excised and closed if possible. If the wound is in the region of the proposed surgical incision, this may be accomplished at that time. If the wound is massive and extensive, careful debridement, irrigation and primary closure of at least the peritoneal cavity must be done with adjacent tissues, mobilized flaps, pedicles, free grafts or prostheses. The norms already established regarding treatment of contaminated wounds must be applied here as elsewhere in the body.

The probability of multiplicity of the wounds especially in relation to the gut is great in this type of abdominal injury. One must never forget that the stomach presents a puncture wound in front most likely has also been perforated posteriorly. Numerous perforations of small bowel or colon may occur. Injury to any of the solid viscera is common, alone or in combination with other intra-abdominal wounds. Most thoracoabdominal injuries are of this type and follow gunshot or stab wounds. It is important to keep these features in mind for the implications are obvious.

Careful, thorough examination of the injured areas must be carried out in order that nothing be missed. The open abdominal wound is far more likely to cause injury to major blood vessels. Probably in many instances such wounds are rapidly fatal. Some patients will survive and develop false aneurysms or arteriovenous fistula. Most injuries to large vessels will escape notice at the original exploration, masked by large retroperitoneal hematomata which usually are best left undisturbed. If major vascular injury can be identified or marked extensive circulatory embarrassment of intestine or extremities is present, immediate restoration of vascular continuity by repair, anastomosis, autograft, homograft, or prosthesis is indicated. Little or no time should be spent in search for foreign bodies. Metal is often well tolerated in the soft tissues indefinitely and if troublesome can be approached later. If extensive retroperitoneal bacterial contamination is present, especially if associated with a pelvic or hip joint fracture produced by the same missile, adequate provision must be made for drainage through the flank. Large retroperitoneal abscesses, dissecting extensively are prone to form under these circumstances and a drainage channel is helpful.

General preoperative, operative and postoperative considerations as outlined in some detail under discussion of closed abdominal injuries apply to this type of wound as well.

Summary and Conclusion

Intra-abdominal injuries are of infinite nature, variety and extent. They may occur in the open or closed type of abdominal wound. Their lethal potentiality is great and it is to be constantly remembered that they are *hidden* from view. Intelligent application of reasonably simple methods of resuscitation, clinical, laboratory and x-ray examination will generally point out the correct therapeutic path to follow. In the event of doubt, surgical exploration of the abdomen must be carried out without unreasonable delay.

Current Concepts

Smoking Is Detrimental In Asthma and Emphysema

GUSTAVUS A. PETERS, M.D.

LOUIS E. PRICKMAN, M.D.

Rochester, Minnesota

PATIENTS who have asthma must be advised not to smoke tobacco.¹⁻³ The same advice should be given to patients who have emphysema. The reasons for such counsel are clear and definite. Smoking induces cough and bronchitis, and the latter in turn causes bronchospasm and symptoms of asthma, possibly terminating in irreversible emphysema.

All patients who have asthma already have some degree of bronchitis. When observed bronchoscopically, the membranes are swollen and red and are covered with a protective layer of mucus. The bronchi usually exhibit some degree of spasm. Air passages in such condition are hypersensitive to such noxious stimuli as dust, smoke, fumes, cold air and strong odors. Therefore, it is most unwise and illogical for the patient who has asthma, bronchitis or emphysema to irritate further his bronchial mucous membranes by voluntarily inhaling smoke into an already hypersensitive respiratory tract.

With the aid of high-pressure selling through the mediums of television, radio and printed material, smoking is perhaps the commonest cause of irritation of the respiratory tract. All physicians are acquainted with "smoker's tongue," "smoker's cough," "smoker's throat" and "smoker's bronchitis." When smoking is stopped, these effects clear up promptly in most instances. It is not uncommon to see patients with daily asthma who state they would give anything to get better. They follow their doctor's advice in regard to taking injections, they avoid dust, danders and other allergens, and they use their antiasthmatic drugs conscientiously, yet during all this time they continue to irritate their respiratory tracts with

tobacco smoke. When the patient is advised to stop smoking completely, the comment is often made that he never had been advised before to stop but just to cut down a little on his smoking.

As an irritant to mucous membranes of the respiratory tract, tobacco smoke causes secretion of mucus. Mucus protects membranes from smoke or other respiratory irritants. Many asthmatic patients then cough vigorously to bring up this protective mucus. However, the more they cough, the more mucus is formed and this, in turn, is coughed up, so that a vicious cycle of coughing and wheezing is perpetuated.

One of the most neglected problems in the management of asthma is the control of overcoughing. One of us (Prickman^{3,4}) stressed the impossibility of controlling asthma as long as cough is uncontrolled, no matter what the reason for the continued cough may be. Some patients cough so violently that they fracture ribs or experience tussive syncope. Such patients must be educated to accept mucus as a normal protective covering to be left on the membranes and not to be raised by severe coughing. Any excess of mucus formed in the lower air passages is expelled with the aid of cilia in the bronchi and trachea. When this excess mucus tickles the upper portion of the trachea, the throat should be cleared gently raising only the small amount of mucus in the upper part of the trachea. This mucus often is so thick and dry, or even formed in plugs or casts that it is almost impossible for the cilia to raise it. Likewise, strands of sticky mucus may stretch across the trachea like violin strings. These secretions must be thinned out by means of hydration and expectorants so that they can be raised without coughing.

Thus, anything that causes cough must be avoided, and smoking is one of the commonest

Neuropathic Arthropathy

THOMAS T. TAMLYN, M.D.

Minneapolis, Minnesota

EXTENSIVE painless articular deterioration is usually due to one of three causes: tabes dorsalis, syringomyelia, or diabetes mellitus. The lesion has been reported, however, in a number of diseases which have hypesthesia as a common denominator.

Associated Diseases

This affliction has been reported to occur with paresis, leprosy of the neural type, and cerebral palsies; with spinal cord and posterior root lesions—infectious, neoplastic, and congenital (spina bifida); and with peripheral nerve diseases including toxic neuritis, injuries, and cervical ribs. It has been noted in pernicious anemia and in “congenital indifference to pain.”¹⁻⁴ Robinson and associates² cited poliomyelitis as a possible cause (but did not give a reference). This is the only instance of the disease in the absence of sensory disturbance.

Clinical Aspects

Site.—The large joints of the lower extremity are the most commonly affected. In tabes the knees and hips are most extensively involved and in diabetes the ankle and foot joints.^{1,2} In syringomyelia, on the other hand, arthropathy occurs in the upper extremity, i.e., in the elbow and shoulders. Charcot joints may also occur, however, in the hands, spine, and jaw. The lesions are usually monarticular.^{6,7}

Neuropathic arthropathy appears as a painless joint enlargement through which multiple bony excrescences can be felt. Effusion is uncommon, as are heat and redness. Gross instability and crepitation are characteristic.^{1,2}

The deformity and destruction may develop slowly, but one striking feature is the rapidity with which they are sometimes seen to take place.

Dr. Tamlyn was a resident in medicine, Veterans Administration Hospital and a fellow in medicine, University of Minnesota at the time this paper was written. His present address is 115 East 72nd Street, New York 21, N. Y.

Pemberton⁸ stated that changes may develop more rapidly in this type of arthropathy than in any other form of arthritis. Vertebral collapse with cord compression may result from spinal involvement.^{7,9}

Syphilis.—Charcot joints develop in about 1 per cent of patients with syphilis and in 5 to 10 percent of tabetic patients. They are usually associated with physical, serologic and anamnestic evidence of lues, and are more frequent in tabetic women. They must be distinguished from the less common syphilitic arthritis.^{1,2} Although usually monarticular, they may affect several joints. Goodman⁵ described a patient with changes in both knees, both elbows and the spine.

Syringomyelia.—Neuropathic arthropathy occurs in 25 per cent of patients with syringomyelia.² The most common joints affected are the shoulder and elbow.⁷ The extent of the destruction is not as great as in the lower extremity.¹

A recent review⁹ of twenty-two patients with syringomyelia revealed that seven had arthropathy. In some closely followed cases it was discovered that soft tissue swelling may precede x-ray changes by as much as six weeks. It was interesting to note that 50 per cent of their patients had pain in the joints at some time.

Diabetes.—A Boston group¹⁰ reported arthropathy in seventeen of 20,000 persons with diabetes (1 in 1100). The average age of the patients was fifty-six (thirty to sixty-nine) and they had had diabetes for an average of eleven and one-half years. Three of the patients had positive spinal fluid Wassermann reactions and two had abnormal colloidal gold curves. The cerebrospinal fluid protein was elevated in eleven of fourteen patients; the average was 69 mg. per 100 ml.; none was over 100. Of the seventeen patients, fourteen had other evidence of neuritis, but only four had “neuritic pains.” Two had “diabetic diarrhea.”

Arterial circulation was judged adequate in all but one.

The authors compared findings in diabetes with those in syphilis. They noted that in syphilis the onset is more commonly acute, with swelling, fluid and some pain in the acute stage. New bone formation and sclerosis of bones near the joint are more common in syphilis. Syphilitic Charcot joints are less common in the foot, which is the classic location in diabetes.

Clinically, the earliest change noted in diabetic patients is tarsal swelling with no fluid, heat or pain. This progresses to a thickened, flattened foot with eversion and external rotation.^{2,10} The disease is usually progressive but may become stationary if the neuropathy improves.¹⁸

A distinction should be made between the neuropathic type of arthritis and the more common (but less specific) type of foot disease seen in diabetes. In the latter, evidence of arterial insufficiency and infection are present and there is no apparent relation to presence of neuropathy or to duration of diabetes.¹¹

Pathological Findings

The process begins in the cartilage and in the zone of calcification between the cartilage and the underlying bone. Erosion of the cartilage, with invasion from the pannus by fibrous tissue are early changes. Fractures and marginal lipping occur. There may be extensive resorption of the ends of the bones. Exostoses develop, and extensive, disorderly new bone formation takes place. Joint "mice" are common. Bits of bone and cartilage are ground into the synovium, and the joint ligaments become lax. Ossification of the joint and periarticular structures may take place.^{1,2,6}

X-Ray Findings

The x-ray changes may be deduced from the foregoing. There is enlargement and extensive destruction of the joint with chaotic new bone formation.^{1,2}

Pathogenesis

It is not clear why joints should behave in this manner. Charcot's original publication evoked an immediate controversy between him and Volkmann, resulting in a "German school" and a "French school." Charcot contended that the lesions were due to loss of "trophic influences" from the nerves, while Volkmann and Virchow

maintained that they were mechanical and related to the unmitigated and unperceived traumata which such joints were exposed.

Evidence for the trophic theory is partly by analogy to the atrophy of denervated muscle. Denervated teeth also show some atrophy and more pertinently, sometimes a combination of atrophy and hypertrophy. In patients with nerve lesions occurring early in life, not only muscle but bones fail to develop normally. When the trigeminal nerve is sectioned trophic disturbances of the eye are troublesome, but if the section is made in the medulla behind the point where the sympathetic fibers join the fifth nerve trophic lesions do not occur. Trophic lesions are not generally seen after sympathetic section, however.¹²

It has been suggested that sympathetic innervation exerts its influence through vasomotor control. Some authors even refer to "neural nutrition" by analogy with blood supply to the joints.^{2,7} One of the strongest arguments for trophic influences is the clinical observation that these lesions occasionally develop with prodigious rapidity going on to complete joint destruction within a few weeks. This is thought to be inconsistent with the "repeated microtraumata" theory.

The identity of the trophic nerves is a problem in itself. There is no agreement as to whether they constitute an anatomic entity or a physiologic concept. They have been placed in the lateral horns of the dorsal cord and in the gelatinous substance of the lumbar cord. Others deny anatomic localization; some would equate them with autonomic nerves.

Gardner^{13,14} has made extensive studies of joint physiology and anatomy. He stated that the nerves are small and consequently the intra-articular distribution is uncertain. His studies were made largely in fetuses. He has confirmed the hypothesis that the joints are innervated by branches from trunks which supply the overlying skin and relevant muscles (Hilton's law). There is some overlap in supply, and most of the bundles run with vessels. Pacinian bodies are found around the joints but there is some difference of opinion as to whether or not they are in the joints. Free nerve endings are found in the capsule but not in the synovium.

He indicated his belief that the role of the nerves, apart from proprioception, pain and vasomotor control, is uncertain. He found no evidence for "trophic" function. He observed that the

inical conditions in which Charcot joints occur ways have accompanying nervous lesions of the in, bones, and muscles.

As a matter of fact, there is some evidence that nervation may afford some protection against a related hypertrophic lesion. Stecher and Karnosh¹⁵ made the interesting observation that Heberden's nodes do not develop in a palsied limb. They cited cases of unilateral cord disease, cerebral palsy and peripheral nerve lesions. They discarded the theory that this is due to protection from trauma, because they believe that heredity is the most important factor in the genesis of Heberden's nodes. They suggested that increased blood flow in the defectively innervated limb prevented the development of the nodes.

Experimentally it has been shown that cutting the posterior roots of cats' spinal cords causes Charcot joints in some but not all subjects. If a concomitant joint injury is inflicted, all develop the disease.¹²

The other school has stressed the mechanical etiology. It has been pointed out that a denervated joint has multiple deficiencies. Minor traumata are not perceived and consequently not treated (tested) or even avoided. The absence of proprioceptive sense means that stresses are applied with the joint in a disadvantageous position. In addition, the joint may move beyond its usual extreme positions both because of loss of proprioceptive sense and because of muscle and ligament laxation.^{12,16}

Casagrande and his associates¹⁶ stated that all these factors—loss of pain sense and of proprioception, faulty muscle co-ordination, and continued use of the joint—must be present for a Charcot joint to develop. They cited an interesting experience. They performed joint denervation on three patients with painful ankles. No Charcot changes developed despite continued activity. The authors concluded that normal muscle co-ordination protected these patients.

At the same time these lesions do occur in other situations where not all of these factors are present. The occurrence of Charcot changes in poliomyelitis has already been mentioned. Here muscle tone, which stabilizes and protects the joint, would be decreased. In syringomyelia, on the other hand, the important loss would be that of pain sense; proprioception may be intact.

It is generally true that Charcot joints do not occur in a limb which is maintained at rest, and

this certainly bespeaks an important role for "wear and tear." There are exceptions, however; the changes have been seen in a bed-ridden patient.^{12,17}

Petrie³ reported the interesting case of a twenty-two-year-old woman with congenital indifference to pain. Charcot changes developed in both knees, one hip and the spine. The patient did not have anesthesia. She could perceive and properly identify a pin prick, and her temperature sense was intact. She simply failed to distinguish unpleasant stimuli. Here, proprioceptive sensation and joint support by muscles were present, and the patient must have been aware of jarring and stretching traumata to the joints. It is particularly difficult to see how ordinary activity could have caused serious trauma to the spine which is a securely guarded structure. It is of interest that a spinal fusion was successful in this case. Fusions often fail in Charcot joints due to the usual causes. A study¹⁷ of biopsy material from this patient revealed normal free nerve endings in the skin and periosteum.

A similar case⁴ was reported in a two-year-old child. As he grew older, however, partial pain sense developed; concomitantly his affected ankle showed marked improvement.

In summary, it would appear that combinations of the following are important for the development of neuropathic arthropathy: loss of proprioceptive sense, loss of muscle guarding and co-ordination, loss of pain sense, continued wear, and poorly understood metabolic derangements consequent to interruption of various nervous modalities.

Treatment

Treatment is aimed at prevention of further damage and preservation of weight-bearing function. This is usually accomplished with external braces. Fusion, while desirable, can seldom be accomplished. In one series²¹ the author reported failure of attempted fusion in ten of twelve knees and in all of three hips. Internal fixation has occasionally been satisfactory. Occasionally amputation is necessary and poor stump healing may be a problem.

Treatment of lues and diabetes does not affect the joint problem, although it has been stated that when diabetic neuropathy improves the joints cease to deteriorate.^{10,18}

Improvement following sympathectomy in two cases has been reported,¹⁹ which the authors

attributed to improvement in blood supply. The published x-rays were unconvincing, however, and vascular changes are not generally considered an important factor in this disease. In another case report,²⁰ no improvement was noted following this procedure in a middle-aged diabetic woman. No evidence of circulatory insufficiency was present.

Summary

A peculiar arthropathy, characterized pathologically by degeneration and hypertrophy, and clinically by swelling, crepitation, instability, and painlessness, is found in a variety of nervous affections. The pathogenesis is discussed.

SMOKING IN ASTHMA AND EMPHYSEMA

(Continued from Page 116)

reasons for cough. The condition of any patient with asthma who continues to smoke will become gradually worse over the months and years; conversely, the patient with asthma who stops smoking can be certain of considerable symptomatic relief.

The patient who has emphysema complicating asthmatic bronchitis has a similar problem, but the irreversible changes in the lungs in this condition will not be helped by cessation of smoking. However, such patients usually have a considerable degree of bronchitis, which is aggravated by smoking tobacco. Stopping the smoking reduces the cough and bronchitis. Without coughing and bronchial irritation, the emphysema may not progress. A number of authors⁵⁻⁷ recently have stressed the relationship of emphysema and smoking but remarkably little about this subject has been mentioned in medical textbooks.

Without exception, patients who have asthma or

emphysema should not smoke anything in any amount at any time.

Clinical-Pathological Conference

Sponsored by
The Minnesota Society
of Clinical Pathologists

Donald F. Gleason, Editor
Minneapolis, Minnesota

CASE PRESENTATION

MINNEAPOLIS VETERANS HOSPITAL

SAMUEL NESBITT, M.D., Moderator

REUBEN BERMAN, M.D., Discussion Leader

First Admission (June, 1949).—A twenty-four-year-old white man entered the hospital for excision of a bilonidal cyst. A photofluorogram was interpreted as showing an enlarged cardiac silhouette of left ventricular type, but this was not apparent on the six-foot films. He presented no signs or symptoms of heart disease. The family history was negative, as was the patient's past history. The electrocardiogram was normal.

Second Admission (February, 1954).—He complained of dyspnea and a feeling of substernal pressure on exertion for two or three weeks and a slightly productive cough; there were no chills or fever. His private physician had given him two injections of penicillin. About one or two months previously, he had experienced an episode characterized by diarrhea, malaise and headache for one week.

The temperature was 99.4° F., the pulse rate 76 beats per minute and the blood pressure 120/80. Fine rales were heard over the right lateral lower part of the thorax. The cardiac apex was 11 cm. from the midsternal line. An early, high-pitched, grade 2 diastolic murmur was heard at the left sternal border. A third heart sound was also audible. The circulation time (arm to tongue) was 17 seconds, and the venous pressure was 22 cm. of saline.

Urinalysis was negative. The hemoglobin was 15 gm. per 100 ml. of blood, the leukocyte count ranged from 11,900 to 5,900 per cubic millimeter of blood, with a normal differential count and the erythrocytic sedimentation rate varied from 38 to 23 mm. per hour. Three blood cultures were negative. Brucella agglutinins were absent. The antistreptolysin titer was 500 units. Cardiac fluoroscopy showed a greatly enlarged heart, primarily of the left ventricular type, with some questionable right ventricular enlargement. The electrocardiogram showed low voltage, left axis deviation, nodal extrasystoles and nonspecific changes in the ST and T waves.

He was kept at rest in bed and was given a low-sodium diet and digitalis. Repeated electrocardiograms showed first and second-degree AV block. Use of digitalis was discontinued, and salicylates and penicillin were administered orally. In April, an apical, grade 2 presystolic murmur was heard. The antistreptolysin titer decreased to 50 units and the sedimentation rate became normal. He frequently showed afternoon temperatures of 100° F. and occasionally complained of dull precordial pain. Thoracic roentgenograms showed

decrease in size of the heart. He was dismissed after five months to continue oral use of penicillin at home.

Third Admission (October, 1954).—For one week he had had chills and fever, dyspnea and a cough that produced pink frothy material. His doctor had administered an oral preparation of penicillin, erythromycin, salicylates and cortisone.

He appeared acutely ill. The temperature was 99.8° F., the pulse rate 100 and the blood pressure 120/60. Fine rales were heard over the lung bases. The point of maximal impulse was in the sixth interspace at the anterior axillary line. The pulmonic second sound was loud and duplicated. A grade 1 blowing diastolic murmur was heard along the left sternal border and a grade 1 rumbling diastolic murmur at the apex. Minimal ankle edema was present.

Urinalysis showed 1+ albumin and 1+ sugar, two to four leukocytes and occasional erythrocytes and hyaline casts per high-power field. The hemoglobin was 10.9 gm. and the leukocyte count was 18,750 (80 per cent neutrophils, 16 per cent lymphocytes and 4 per cent monocytes); the sedimentation rate was 110 mm. The antistreptolysin titer was 625 units, and the C-reactive protein was 4+. The electrocardiogram showed a wandering pacemaker, premature ventricular contraction, second-degree AV block, and changes in the ST and T waves. Thoracic roentgenograms showed increase in heart size and changes consistent with pulmonary edema.

He received blood, penicillin, cortisone and digitoxin. The temperature remained normal except for an occasional afternoon rise to 99° F. In about two months, the sedimentation rate was normal and the antistreptolysin titer was 250 units. Within three months, the C-reactive protein was negative. Use of cortisone was discontinued and he was dismissed after four months in an improved state.

Final Admission (May 10, 1955).—Soon after dismissal, he noted epigastric pain associated with nausea, vomiting and diarrhea, which persisted. He appeared acutely ill. The temperature was 100° F., the pulse rate 80 and the blood pressure 110/80. Moist rales were heard over the lung bases. Examination of the heart was as previously described. There was minimal ascites and a tender liver edge was felt four fingerbreadths below the costal margin. The spleen was not palpable. There was no peripheral edema.

Urinalysis revealed albumin 3+, five to seven leukocytes, one to two erythrocytes and occasional coarse granular casts per high-power field. The hemoglobin was 13.1 gm. and the leukocyte count was 10,400, with a normal differential count; the sedimentation rate was 35 mm. The serum amylase was 58 units. Stools were negative for occult blood. The antistreptolysin titer was 333 units. Five aerobic and anaerobic blood cultures were negative. The thoracic roentgenogram showed further increase in heart size. Roentgenologic studies of the abdomen and upper part of the gastro-

Published with approval of Chief Medical Director. The statements and conclusions published by the authors are the result of their own study and do not necessarily reflect the opinion or policy of the Veterans Administration.

intestinal tract showed no abnormalities. The electrocardiogram disclosed first-degree heart block, occasional ventricular premature contractions, low voltage, and left ventricular strain or digitalis effect or both.

Thorazine was administered and use of digitoxin was discontinued for three days, after which his complaints subsided. On the fifteenth day, he complained of generalized abdominal pain that became localized in the right lower quadrant, where muscle spasm and rebound tenderness were noted. The leukocyte count was 13,000. Appendectomy was done with the patient under local anesthesia. The pathologist's report was subsiding appendicitis. Ascitic fluid (800 ml.) removed at operation showed a specific gravity of 1.020 and a value for protein of 3.7 gm. per 100 ml. This fluid contained four leukocytes and 4,160 erythrocytes per cubic millimeter. Culture was negative.

Immediately after operation, the blood pressure decreased and the patient required levophed and aramine for two days. He became oliguric and remained so. Three weeks following operation, the blood urea nitrogen was 17 mg. per 100 ml. and the carbon dioxide was 18.9 mEq. per liter; values for chloride, sodium and potassium were 91, 123.4 and 7.4 mEq. per liter, respectively. Jaundice was observed and the serum bilirubin was found to be 1.1 mg. per 100 ml. at one minute, with a total of 3.5 mg.; the cephaline flocculation was 2+ and 3+, the thymol turbidity was 2.8 units and the alkaline phosphatase was 11 King-Armstrong units. Peripheral edema was noted, as well as reaccumulation of ascitic fluid. His condition deteriorated steadily and he died thirty-four days after operation.

Discussion

DR. REUBEN BERMAN: A common alibi raised at these conferences by the discussor is that he would have done so much better had he seen the patient. I am told that I did see this patient, so my alibi is destroyed; however, I do not remember him.

In 1954, the patient had an illness characterized by prodromal symptoms of diarrhea, malaise and headache, followed soon by dyspnea, fever, an enlarged heart and rales at the right base. At the onset of these cardiac findings, he had a high-pitched, grade 2 diastolic murmur, normal circulation time and increased venous pressure. The urine was normal. The sedimentation rate, antistreptolysin titer and C-reactive protein were increased. Perhaps at this point we ought to see the roentgenograms.

RADIOLOGIST: The first films are dated December, 1954, and were taken during the third admission. There is definite cardiac enlargement, with predominance of the left side of the heart and only mild left atrial enlargement. In May, 1955, the heart had enlarged further and again the enlargement is about the same configuration. It would not be possible to rule out pericardial effusion. In June, 1955, the picture is the same. As far as the heart silhouette goes, the radiologist would consider either a mitral lesion, combined with either myocarditis or pericardial effusion, or possibly mitral stenosis and aortic stenosis, which are less likely.

DR. BERMAN: A presystolic murmur was heard later in his illness. The antistreptolysin titer decreased and the sedimentation rate became normal. I assume that a diagnosis was made of acute rheumatic fever with defects of the aortic and mitral valves. He apparently improved during the summer. He came in again

obviously in cardiac decompensation. The same diastolic murmur was heard at the base and a rumbling diastolic murmur was present at the apex. Now he had an abnormal urine, with 1+ albuminuria that could represent the albuminuria associated with heart failure.

Here is a person who apparently was well until the spring of 1954, when he acquired an illness characterized by acute prodromal symptoms of malaise and diarrhea. He came into the hospital with a large heart and some murmurs. The heart got a little bigger and then smaller; again it enlarged and was associated with a high sedimentation rate and increases in C-reactive protein and antistreptolysin titer. He had a diastolic murmur heard first over the base, suggesting aortic insufficiency, and later at the apex, suggesting mitral stenosis. The indications are overwhelming that this man had acute rheumatic fever associated with endocarditis manifested by these two valvular lesions. The surprising thing was the fact that, with normal blood pressure and only a faint diastolic murmur, the man was in heart failure. He was extremely sick and yet had minimal valvular lesions. Subacute bacterial endocarditis with attendant anemia and toxemia occasionally will cause an otherwise compensated heart to decompensate. We have no evidence in this case that endocarditis was present. More likely this man continued to have acute rheumatic fever, with rheumatic myocarditis and, in all probability, pericarditis—in other words, rheumatic pancarditis. The main reason that his heart failed was myocarditis, the effect of the valvular lesions being minimal.

The final admission is most interesting because he came in with findings suggestive of acute surgical abdominal disease. He also had an enlarged liver, which he did not have before. The antistreptolysin titer again increased. This is the first time I have thought I could get some value out of the antistreptolysin titer and C-reactive protein. He was given Thorazine and had some jaundice afterward. A diagnosis of acute appendicitis apparently was made and appendectomy was done. The findings were ascitic fluid with a high specific gravity, a large number of erythrocytes and a negative culture. His blood pressure decreased after the operation and he became oliguric. He had a normal blood urea, decreased carbon dioxide, chlorides and sodium, and increased potassium.

I am interested in the shock associated with low chloride and high potassium values. I am wondering if this man had an adrenal crisis. My diagnosis is rheumatic fever with pancarditis, especially myocarditis, and slight mitral stenosis and aortic insufficiency. The terminal event was recurrence of rheumatic fever with rheumatic peritonitis.

DR. FLINK: The increased potassium could be explained by heart failure alone, with a low pulse syndrome. We have seen examples of this, the most frightening of which involved a man with tuberculous pericarditis who had a striking electrolytic pattern suggesting adrenal insufficiency. His potassium was even greater than in this case and his sodium was about the same.

DR. SMITH: I would like to ask if the internists find any comfort in the pathologist's report of subacute appendicitis.

DR. BERMAN: Subacute appendicitis does not mean anything in the face of the ascites and the exudative character of the fluid.

DR. GLEASON: That diagnosis should have read probable minimal subsiding appendicitis.

DR. SMITH: If one of us were presented again with a case similar to this, what would we feel would be the minimal requirements for laparotomy?

DR. BERMAN: In the face of all the other medical problems, I would be loath to recommend appendectomy, regardless of the findings.

DR. HALL: Some things about this case are peculiar if you are going to call it rheumatic fever. The onset was rather strange. Rheumatic fever seldom starts with diarrhea; it more often starts with a sore throat. Furthermore, in all these episodes we heard nothing about any joint pains or signs of joint inflammation. In the third admission it was stated that he had chills and fever; it is indeed unusual to have shaking chills in rheumatic fever in spite of the fact that the patient may be febrile. This man undoubtedly had some form of myocarditis and, if we are to believe the report that he had these diastolic murmurs, I suppose we have to presume that it was rheumatic but I think it is a strange case of rheumatic fever.

DR. SMITH: I would like to ask Dr. Hall if the antistreptolysin titer would be compatible with other possibilities than rheumatic myocarditis. Given myocarditis and these antistreptolysin titers, what other possibility would you consider?

DR. HALL: These titers certainly support strongly the diagnosis of rheumatic fever but they are not entirely specific. The antistreptolysin titer increases in any kind of streptococcal disease, as well as in many other conditions, so this test certainly is not specific for rheumatic fever.

QUESTION FROM AUDIENCE: How frequently does 3+ albuminuria result from cardiac failure alone?

DR. BERMAN: It is very common.

Discussor's Diagnosis: 1. Rheumatic pancarditis, with valvulitis, mild mitral stenosis, mild aortic insufficiency, myocarditis and probable pericarditis; 2. Probable rheumatic peritonitis.

Ward Physicians' Diagnoses: 1. Rheumatic pancarditis, as above; 2. Possible viral myocarditis.

Pathologic Aspects

DR. GLEASON: Necropsy disclosed 2+ edema of the lower extremities and five liters of dark but clear yellow fluid in the abdomen. About 100 ml. of similar fluid was present in each pleural cavity, with no unusual

amount in the pericardial cavity. The pericardial surfaces were smooth and glistening.

The heart weighed 550 gm.; the muscle of all four chambers appeared to be hypertrophied. The inferior vena cava, superior vena cava and pulmonary veins were definitely dilated. All the cardiac valves were practically normal. One aortic valve had slight thickening at the edge of one leaflet. There was no evidence of stenosis nor insufficiency. One mitral valve had a small, thin, flat plaque about 1 cm. in diameter on the broad part of the leaflet. There were no verrucae to suggest rheumatic disease. The chordae tendineae were not thickened. The myocardium was paler and a little softer than normal. The coronary arteries showed minimal atherosclerosis.

The lungs were only slightly increased in weight. The liver was normal in weight but was markedly "nutmeg" in character. The right kidney weighed 200 gm. and the left weighed 225 gm. The right kidney contained several infarcts that were pale and beginning to shrink; they probably corresponded closely in age to the time of the acute abdominal episode. One of them was in the anterior aspect of the lower pole and could well have accounted for the entire episode. The gastrointestinal tract was entirely normal. The aorta showed minimal atherosclerosis. One small mural thrombus was present in the left iliac vein just as it entered the vena cava.

Microscopically, the only striking change in this case was in the myocardium, in which there was diffuse fibrosis between the myocardial fibers (Fig. 1). This fibrosis was present in all portions of the heart. There were practically no leukocytes to be seen, so it was not an exudative process. It was a simple bland fibrosis occurring uniformly between muscle fibers and not concentrated around small arteries, as would be expected in rheumatic lesions.

The microscopic appearance raised many possibilities. Azocarmine stain showed that practically all the tissue between the fibers was collagen. A slight concentration of connective tissue was noted beneath the endocardium but nothing even approaching what has been referred to as "subendocardial fibro-elastosis"; in addition, special stains showed no elastic component in the diffuse scarring. Stains for amyloid likewise were negative.

The rest of the pathologic changes were incidental to the congestive heart failure or unrelated to the basic disease. There was severe central atrophy of the liver, enough to account for the jaundice and the abnormalities in liver-function tests. Sections of the lung showed some pulmonary congestion and early bronchopneumonia. The lungs did not contain many "heart-failure cells." The kidney infarcts were fairly old. There were no mural thrombi in the heart to account for these; it is possible that they came from thrombi in pulmonary veins.

Nothing about this case from the pathologic aspect really bears any resemblance to rheumatic fever. Valvular changes were minimal. Pericarditis was absent. Aschoff nodules were absent and the myocardial scars were not perivascular. None of the other stigmata of rheumatic fever were present. Stains for amyloid were

negative and the process did not look like amyloid. It was fibrillar. It was not an exudative process like Fiedler's myocarditis or any of the other myocarditides. Leukocytes were absent in the sections. The possibility

ported on copper deficiency in cattle and these cattle have interstitial cardiac fibrosis. Severe hyperthyroidism and hypothyroidism have been associated with some interstitial myocardial fibrosis of the myocardium. This

Fig. 1.

was raised that it could be healed exudative myocarditis, but it would have to be completely healed and it is difficult to believe that exudative myocarditis of this extent, as evidenced by the scar that was left, would have permitted the patient to survive. Exudative myocarditis often shows scanty inflammatory infiltrate and yet prove fatal.

One possibility in this case is scleroderma. The heart involved in scleroderma looks like this but it would be impossible to prove a case of isolated scleroderma of the heart. It is also possible that this is actually some kind of congenital process. Dr. Bell favors this concept, in the sense that the mesenchyme in which the heart originated did not differentiate completely into muscle and this residual tissue eventually compromised the function of the heart. This is an interesting idea because, about the same time this case was being reviewed, autopsy material was received from another VA Hospital in a case in which a clinical diagnosis of Fiedler's myocarditis had been made. That heart showed the same changes as in this case. The man was twenty-six years of age and had had idiopathic heart failure for about nine months before he died. His sister is now suffering from idiopathic heart failure, he had a brother who died at age twenty of heart trouble of unknown type and his mother died at about age thirty of heart trouble of unknown type.

Animal work suggests that interstitial fibrosis eventually occurs in vitamin B₁ deficiency. The few beriberi hearts that Dr. Bell has seen showed a little edema between the fibers but certainly nothing like the changes in this case. Australian veterinarians have re-

ported on copper deficiency in cattle and these cattle have interstitial cardiac fibrosis. Severe hyperthyroidism and hypothyroidism have been associated with some interstitial myocardial fibrosis of the myocardium. This patient had no signs of thyroid disease and his thyroid was normal at autopsy. Exposure to x-rays in animals has produced interstitial fibrosis that resembles this somewhat. Long-standing acromegaly sometimes is associated with interstitial myocardial fibrosis. Experimentally, various drugs such as digitalis given to excess and adrenalin given over long periods have resulted in some interstitial fibrosis. However, none of these factors seem to apply in the present case.

Final Anatomic Diagnoses: 1. Idiopathic, diffuse, interstitial myocardial fibrosis; 2. Chronic passive congestion of liver; 3. Infarcts of right kidney.

DR. SMITH: I would like to comment on the murmurs. This man undoubtedly had aortic insufficiency but I do not know the genesis of the insufficiency. It conceivably could be due to an enlarged aortic root from the general dilatation. I would like to know Dr. Gleason's opinion of the pathogenesis of this process. Do you think that the myocardium became collagenous without going through a stage of some myocardial necrosis or do you feel that the myocardium ever was involved?

DR. GLEASON: Study of field after field of the sections, which all look the same, shows that muscle fibers are not missing. It does not appear that muscle fibers became necrotic and were replaced by scar. It does appear that the connective tissue arose slowly around the fibers or at least was there for an extremely long time.

MEDICINE'S CONTRIBUTION TO WORLD PEACE

Medicine is universally recognized as one of the great world-wide arts and sciences that bind humanity together with a language and a purpose transcending all differences of race, creed, or color.

To make the language of medicine more articulate in the cause of international peace and human progress, the doctors of the free world are united in the World Medical Association, the membership of which now embraces fifty-three national medical societies.

But it is never enough to establish great institutions. Only when individuals are given an opportunity to play an active part does any human organization come alive and begin to realize its basic purposes.

Every American doctor knows first hand the vital role he may play in guarding and protecting his profession by becoming an active member in his county, state, and national medical society.

Today, every American doctor has the opportunity and the imperative challenge to help make his profession a stronger influence for world peace. This he may do by joining our own United States Committee of the World Medical Association.

Similar supporting committees have been organized in a number of other leading nations, whose national medical societies, like the AMA, are members of the World Medical Association.

In a timely action, the World Medical Association at its Tenth General Assembly in Havana in October adopted a six-point program to implement some of its constitutional purposes: to promote world peace. This program includes a development of mutual exchange visits of foreign doctors; exchanges of distinguished medical teachers; establishment by each World Medical Association member (national association) of an International Visitors' Bureau; stimulation of visits by representatives of member associations to the annual meetings of other member associations; holiday exchange programs between doctors and their families; and exchanges of textbooks and medical and scientific publications.

To implement this program takes money and interested members. You may play your part by

joining the United States Committee of the World Medical Association. Active membership dues for 1957 are \$10.00. This membership also makes you the recipient of the medical journal published by the World Medical Association. This is a monthly publication and contains, not only scientific articles, but news of medical progress on a world-wide basis.

Every member of our State Medical Association is urged to do his part in the promotion of world-wide peace and human understanding by joining the World Medical Association. Contact your county medical society officers or the state office for membership applications.

THE PSYCHIATRIC SOCIAL WORKER IN PSYCHOSOMATIC MEDICINE

In a previous editorial it was noted that certain patients with somatic symptoms benefit from the treatment approach of the psychiatric social worker functioning in a clinic setting. This was true of a patient for whom a psychiatric social worker, in consultation with the psychiatrist, assumed major responsibility for treatment.

The patient's presenting somatic and almost disabling symptoms of suffocation, chest pains and near black-outs had precipitated a severe anxiety state. The diagnostic conclusions, formulated by the clinic team, accurately assessed the advisability of assigning this patient to a psychiatric social worker. The factors particularly important in reaching such a decision were: (1) The patient, who readily engaged himself in the therapeutic relationship, manifested from the beginning a desire to focus on what could be so disturbing to him in his environment. (2) Personality disintegration did not have to be dealt with as the patient had not yet created any serious problems in his work and family situation. (3) The patient in his initial relationships with the clinic demonstrated a desire to better understand himself, but rejected a plan of treatment by the psychiatrist with whom the primary focus of treatment would have been on the resolution of inner conflicts.

The patient rapidly developed a healthy secure feeling within the socio-psychiatric oriented therapy of the psychiatric social worker. He was

then able concurrently to utilize drug therapy under direct supervision of the psychiatrist for alleviation of the near-panic anxiety state. Following this, the patient could deal openly and intensively with the meaningful factors in his family and work experiences. This temporarily became a real hurdle for this patient as the therapeutic process revealed that his personal and work life had been, and continued to be, successful and satisfying. However, the focus in treatment on the reality situation and environment remained constant, and the seeming hurdle offered the opportunity for the inclusion of the patient's wife in the therapeutic experience. Traditionally, the psychiatric social worker is skilled in working with family members and also in clearly maintaining her objective in working with them—which is to facilitate treatment of the patient. In the case of this patient, several interviews with his wife resulted in providing the first real clue to causation in the patient's disorder. Several weeks had to elapse before the patient was ready to deal with the knowledge the therapist possessed. It was at this time that the psychiatric social worker's knowledge of dynamics and the constant availability of psychiatric consultation were particularly important. The patient had to be helped to look superficially but sufficiently at what, in his present situation, was reactivating the repressed painful feelings of earlier life experiences. He also had to be helped to recognize such feelings were now being expressed with such severe physical symptoms. During this period of treatment the wisdom of having this patient seen by a psychiatric social worker was repeatedly manifested, for the patient would have turned the focus of treatment "inward" more than "outward" because of a temporary focus on inner conflict. More than a temporary focus "inward" could have precipitated some personality disintegration and thereby damaged some of this patient's emotional health. Since the psychiatric social worker's orientation is "outward," this danger was averted.

With the maintaining of the appropriate focus in treatment this patient was helped to give up his almost disabling somatic symptoms and modify his behavior so he could make the most productive use of his personal and environmental resources.

CURRICULUM OF THE MEDICAL SCHOOL

At the present time the Medical Student Committee at the University of Minnesota is studying the curricula of several other medical schools throughout this country. An attempt has been made to select the so-called best schools in the country and a few other schools which are outstanding for various reasons. So far, this has been entirely a student project except that the opinion of the faculty was sought to help select schools.

The original purpose of the survey was twofold: First, to compare time spent at this school with time spent at other schools in an effort to evaluate critically the need for the summer session at Minnesota; second, to study other schools purely because of interest in medical education.

The survey is still at a very immature stage. It is mentioned here solely for one purpose, namely to indicate the interest that medical students feel in the curriculum. We feel that by the time a medical student has finished his course he knows the curriculum better than anyone, including faculty members who mapped it out on paper. Admittedly, the student does not know what should be taught as well as a faculty member might, but that is not the point. The point simply is that the student should be better able to estimate wasted time. By wasted time we mean excessive repetition of material from course to course between departments. We think that departments which do not make use of the time allotted to them, e.g., lecturers who fail to show up to give the lecture, are also wasting time.

Repetition and wasted time do occur. We think that they occur here at Minnesota, not excessively but often enough so that we feel that some of the time spent in summer sessions could be eliminated. Summer sessions have long been a tender subject to medical students at Minnesota. Income lost by having to attend school during the summer is often a real source of financial embarrassment. The student here further criticizes the present program because the free periods which were set for Tuesday and Thursday afternoons when the summer session was instigated are not observed by many departments.

The Medical Student Committee has been concerned with the summer sessions since its inception.

This is the fourth in a series of editorials concerning the medical student.

on. We hope to obtain some convincing evidence that the summer session at its present length is dispensable in at least one of the years in medical school.

ON CHARITY DRIVES

How long has it been since you last voiced a complaint on the number of charity drives one encounters in the course of a year's time? Perhaps it was last month when you received your Christmas Seals in the mail. Maybe it was yesterday when a solicitor called on you for the March of Dimes. Or it could be as long ago as that week last fall when you were "hit up" for a contribution to the YMCA, Sister Kenny fund, Salvation Army and Boy Scouts—all in one week. There is the possibility you are one of those unusual citizens who truly finds joy in giving and helping others. We hope so.

But if you aren't, perhaps the argument that you have been "over-burdened" deserves some analysis. After all, there's no sense in nursing a grudge; a person might as well decide whether he wants to do his part gladly, or forget about charities altogether.

Is society really "overburdened" with charity drives? Check the following list and see if your answer gives a key:

Have you ever been able to claim more than the 10 per cent automatic deduction for charity on your federal income tax? (Federal tax authorities say that very few ever do.)

Have you ever had to forego purchasing something you wanted or needed badly because you have the money to a charity? (We'll bet you haven't.)

Have you or your family, or a friend or a relative ever benefited substantially from a charity? (Be careful before you say "no" to this one. Just think of the progress in fighting disease and human hardship which has been accomplished by the nation's charitable organizations.)

Would you truly prefer that there be no charity drives so society could return to the Dark Ages when tuberculosis and polio were rampant, youth recreational needs were ignored, severe suffering due to poverty was commonplace and no one came to the rescue when disaster struck? (We doubt it.)

Do you believe these vast charitable enterprises should be taken over by the government?

This appears to be the only alternative, and we hardly believe the government could do the same job as cheaply and as well.

Think of these questions the next time someone calls on you for a contribution. It may make it easier for you to "do your part"—with a smile instead of a grimace. And it may make you feel a lot better inside, knowing that your small gift will never be missed, and together with the gifts of millions of others, will really amount to something worthwhile.

—Reprinted from the *Worthington Daily Globe*, January 19, 1955

LIGHTING THE DOCTOR'S OFFICE

Perhaps in few professions is the dependence on sight as vital as in the medical profession. When one considers that sight and light go hand-in-hand, one equally dependent on the other, the realization of the importance of good lighting to the field of medicine becomes increasingly apparent.

In addition to its functional importance in both examination and treatment, the psychologic effect of lighting on the patient should not be overlooked. The professional man who gives serious thought to proper lighting in his office adds substantially to his chances of success. Increased office efficiency and more attractive surroundings to his patients are contributing factors.

Since several areas in the average doctor's office are used for quite different purposes, distinctly different lighting techniques should be employed. In some cases, they are primarily decorative and in others utilitarian, depending on the function of the room.

Although a doctor's office may be in a commercial office building or his home, in a separate dwelling or an apartment house, it will have little bearing upon the lighting methods recommended for various rooms and work areas.

Reception Room—A patient's first contact with the office is the reception or waiting room and it should be planned with his comfort in mind . . . free of all aspects of the medical profession. Whether there is a nurse-receptionist present or not, a friendly reassuring atmosphere will do much to calm "waiting room nerves." Much can be done with the room's decor, but well-planned lighting plays an important role too.

Floor and table lamps properly placed help create a homelike atmosphere. Their very familiarity subconsciously helps to reassure the nervous patient. Fluorescent ceiling fixtures alone might provide higher light levels at less cost, but the effect, physically and psychologically, might be professional and cold.

Magazine reading is a favorite pastime among patients waiting for appointments. Reading lamps should provide plenty of light without the discomfort of eyestrain. Any bright source of light which comes into the line of vision can be most annoying, especially to those just sitting. For this reason, all lamps should be equipped with white translucent bowls to diffuse the light source. In addition, attractive transparent shades should be added for a more pleasing decorative effect. White is best for illumination.

For reading, 100 watts are recommended with a six-inch bowl and 150 watts for an eight-inch bowl. If it is a three-way switch, 50-100-150 watts are favored. Floor lamps require 100-200-300 watts in a three-way light.

Sylvania Electric Products, Inc.

MINNESOTA HUMAN GENETIC LEAGUE

By authorization of the Board of Regents of the University of Minnesota, the Charles Fremont Dight Institute for the Promotion of Human Genetics began to function on July 1, 1941, under the supervision of a director, Professor C. P. Oliver, and an advisory committee. Theodore C. Blegen, Dean of the Graduate School, has served as chairman of the Advisory Committee during the fifteen years of its existence. Two other "charter members" of the committee are still serving faithfully, Dwight E. Minnich, Chairman of the Department of Zoology, and Donald G. Paterson, Professor of Psychology.

Under the vigorous direction of Professor Oliver, the program of teaching, research and public counseling and information was initiated promptly. The first bulletin of the Dight Institute contained a report by the director on the organization and aims of the Dight Institute and a biographic sketch of Dr. Dight by Dr. Evadene B. Swanson. This biographic gem has provided the facts about

Dr. Dight which the present writer has included in this account.

It was not until 1944 in the third bulletin of the Dight Institute that the following sentence appears, "The subcommittee on eugenics societies has been corresponding with various American eugenics societies and is preparing plans which we hope will interest a group in organizing a eugenics society in Minnesota." Outside assistance failed to materialize and it became clear that the precise type of organization which Dr. Dight had envisaged was not the answer to the need. The problems were not as simple, nor the solutions as easy, as Dr. Dight had thought. Attempts to provide legislation regulating the reproduction of the public were not likely to succeed until more research had been done both on methods for controlling reproduction and in the basic science of human genetics. Consequently, the immediate need was for basic research in human genetics and interpretation of the results to the medical profession and the general public. Obviously, the first person who needs to be informed of discoveries from related fields concerning reproduction and health is the physician. From him the patient meaning the public, should receive the proper instructions and information about genetic problems.

It was decided that a modern "research oriented" society would be established without ties with any other group. Public education would be devoted to the wider dissemination of knowledge concerning human genetics, eugenics, and population problems.

The organization was to be called the Minnesota Human Genetics League. The articles of incorporation were filed on October 26, 1945. The president was Dwight E. Minnich, the treasurer, Theodore C. Blegen, and the secretary, Clarence P. Oliver.

This time there was to be no lack of participation by prominent citizens generally to be found working for all good causes. Professor Minnich approached the late Miss Helen Bunn of St. Paul, Mrs. Dorothy Atkinson and Mrs. John Cowles Sr., of Minneapolis, with the request that they become patrons of the League. They not only agreed to do so but gave generously of their time and energy in the work of the League over the years. Miss Bunn left a gift of \$10,000 to the Dight Institute of the University as one of her three bequests for the public good. Physicians and other prominent citizens joined the new organiza-

This is the fourth in a series of editorials on the Minnesota Human Genetics League.

on and have given it steadfast support during its decade of growth.

No provision was made for a paid secretary, but a partial solution was found in the willingness of the director of the Dight Institute to accept this burdensome job. The new Society was launched, and it would seem that the pitfalls which led to the disintegration of the old one had been avoided.

The Dight Institute for Human Genetics

BELL SOLAR BATTERY

Each day the sun pours on the earth as much energy as is contained in all the reserves of coal, oil, natural gas and uranium—and yet man has been unable to put this power directly to use. However, a step has been made in this direction by means of a solar battery developed by the Bell Telephone Laboratories. It is the first successful device which can convert the sun's energy directly and efficiently into usable electricity.

A laboratory model of the Bell solar battery was first demonstrated to the public at a meeting of the National Academy of Sciences some two years ago. At that time, the battery achieved a six per cent efficiency in converting sunlight directly into electricity. This compared favorably with the efficiency of steam and gasoline engines, in contrast with other photoelectric devices which have never been rated higher than one per cent.

With improved techniques, scientists at the Bell Laboratories have been able to increase this efficiency substantially—from six per cent to eleven per cent. Nothing is consumed or destroyed in the energy conversion process and there are no moving parts, so the Bell solar battery should last indefinitely.

The solar battery uses strips of wafer-thin silicon about the size of common razor blades. These strips are extremely sensitive to light. They can be linked together electrically, and can deliver power from the sun at the rate of 50 watts per square yard of surface. The specially-prepared silicon is obtained originally from common sand, one of the world's most abundant materials. The battery, along with other silicon devices, resulted from a broad fundamental program at Bell Laboratories for studying silicon and its possible application in modern electronics.

This is the fourth in a series of articles on the telephone.

Although work is still in the experimental stage, actual use of the Bell solar battery in the telephone business is a strong possibility. Down in Americus, Georgia, a solar battery is being tried as a battery charger at amplifier stations along a rural telephone system. This system, using Bell-invented transistors, points to greatly increased service on rural telephone lines.

No one knows what other uses will be found for the solar battery, but there are indications that it may some day serve mankind in a variety of ways. One company is experimenting with a sun-powered traffic light using the Bell solar battery and a suitable power-storing device. And, an automobile manufacturer has developed miniature cars using the solar battery to supply power to batteries.

NORTHWESTERN BELL TELEPHONE COMPANY

CHANGING CONCEPTS IN THE TREATMENT OF TUBERCULOSIS

Principles of Rehabilitation and Vocational Training

One of the effects of modern therapy has been to make our patients intolerant of long-continued rest. This is both bad and good; bad, because every patient still requires an amount of rest dictated by the extent of disease and toxemia at diagnosis, and by the form of treatment applied; good, because far too many in the past have been so imbued with the necessity for rest, and more rest, that they have lost the will and capacity for work. Man does not live by bread alone, but he requires bread, and he will be morally and psychologically supported if his bread comes from his own labor and not from charity. He may exist in the static conditions outlined in advice on rest, good food and the wise use of leisure, but he will not live in them; moreover, such advice requires a sound economy, and a mind that is either bovine, or strictly controlled by a philosophy usually too hard to acquire for the man, in such circumstances, whose pleasure in life depends on his active accomplishments.

It follows that what is called occupational therapy should be replaced as soon as possible by therapeutic occupation. The forty years' experience of Papworth has proved that the patient is seldom able to make his living by the products of diversional therapy. Such therapy is preparatory;

This is the ninth in a series of articles on pulmonary tuberculosis.

it should never be an end in itself; this applies to the student as much as to the machine minder or the secretary. By and large, the patient fit to be up all day and to take one hour's exercise is fit to start sedentary occupation in the sheltered conditions of the factory or the office at three hours per day, provided he spends the rest of the day as outlined by his physician.

Subsidization is justified only for the patient so disabled that he cannot get the basic necessities of life by his own efforts. To supply it without attempts to assess work-potential is misplaced generosity; to continue it without regular reassessment is to invite fraudulent use of charity or of government aids.

A scheme which recognizes these dangers is found in grants-in-aid over a definite period, during which both work-potential and the physical response to sheltered work and continued treatment can be re-examined at regular intervals. Training should be progressive at the rate for the individual, both in hours of work and in successive branches of the new trade. It was from his experience of such progress among his colonists that Varrier Jones said that "work creates hope, and hope creates vitality."

During this progress a true categorization of patient-workers will emerge. Some will be found totally unfit for industrial conditions in either sheltered workshops or open industry; for them home-work with subsidization is a necessity. Some will show a capacity for sheltered work at a few hours work per day and will require such work near their homes in order to avoid the fatigue of travel in tiring conditions. Others will show they can work seven to eight hours a day in a Settlement; among these are many who remain infectious. The majority will, within two years of commencing work, regain full working capacity in open industry, and remain sputum-negative as a result of their continued active therapy on sanatorium lines during nonworking hours.

Such a sifting process is full of the unexpected. While, by the patient application of trial and error, it may disclose the sad loss of functional ability as out of proportion to the physical, it can also develop the moral fiber of a man who has accepted a grave physical disability, but is determined to overcome it.

RICHARD R. TRAIL, M.D.
London, England

BLUE SHIELD ACTS TO MEET NEW CHALLENGES

Ten years ago, forty-five struggling local Blue Shield Plans had a combined enrollment of less than 2 million people. Today, 73 Blue Shield Plans cover some 38 million; and if their present rate of growth is maintained, these Plans will pass the 40 million mark in enrollment during 1957.

Several factors have conspired in recent years to alter and complicate the basic problems of Blue Shield enrollment: For one thing, most of the windfall apples have fallen off the tree, and enrollment men are having to climb ever higher in the tree to fill their baskets. Most local "blue chip" industrial groups have long since been enrolled by Blue Shield or some other agency, and the remaining local prospects are predominantly small groups, the self employed and rural dwellers.

Another vital new factor has been introduced by the tremendous growth of new industrial giant resulting from corporate mergers, and the concomitant tendency of labor unions to negotiate welfare benefits on a national scale. These big corporations and unions are demanding nation-wide hospital and medical care programs, offering at least the same scope of benefits for their workers in all parts of the country.

Blue Shield is an association of strictly autonomous local Plans, having similar purposes, but offering a considerable variety of specific benefits. The Constitution of Blue Shield Medical Care Plans recognizes that "state and local medical care plans should be autonomous in their operations so that the needs, facilities, resources and practice of their respective areas can be given due consideration, but that the health and welfare of the public is advanced by the co-ordination . . . of methods, coverages, operations and actuarial data."

The Plans have sought, by voluntary agreement to co-ordinate their efforts and to develop a basic program which each local Plan may offer to its members of inter-Plan groups within their local Plan areas.

Without sacrificing an iota of local independence, more than three-fourths of the Plans have recently reached agreement on a standard scope of Blue Shield benefits, all or any of which each Plan will make available to any group of subscribers desiring this pattern of benefits. Nearly all the

Medical-Legal Opinions

JULE M. HANNAFORD, Legal Counsel
Minnesota State Medical Association

OBTAINING CONSENT OF PATIENT FOR SURGERY

An operation may not be performed upon a patient without first obtaining the consent of the patient or of someone authorized to act on his behalf, *Mohr vs. Williams*, 95 Minn. 261. However, a consent is not always valid and will not, therefore, protect a physician in every case. For example, a consent may be invalid (1) because it authorizes an unlawful act, i.e., an abortion not medically necessary; (2) because it is given by a person who has no right to give consent, i.e., a person mentally incompetent; or (3) because it was obtained by misrepresentation or fraud, i.e., representation that an operation is necessary when such is not the case or that an operation will give greater relief than can reasonably be expected.

Moreover, consent will not protect a physician unless the operation is performed strictly within the limits of the consent given. Thus, consent is no defense if in the course of an authorized operation a physician performs a different or a supplementary operation which is not necessary to protect the patient's health or life.

There is no legal requirement that a patient's consent to be valid must be in writing. Consent may be implied, oral or written. An implied consent results when an adult of sound mind is fully informed by his physician as to an operation that is to be performed and then co-operates with his physician in bringing it about. It is under the legal concept of implied consent that a physician is permitted in an emergency to operate on a delirious or unconscious person. An implied consent, however, necessarily leaves open to question the exact extent of the consent and may be difficult to prove in case of controversy. A physician who operates in an emergency on the basis of an implied consent should realize that if litigation ensues he will have to prove that an immediate operation was necessary, that an express consent could not be obtained from the patient or someone authorized to consent for him without endangering his health or life and that the operation performed was only such as was necessary.

Oral consent is, of course, consent by word of mouth. Ordinarily it is supplemented by an implied consent resulting from the co-operation of the patient with the physician in the performance of the operation. An oral consent may, however, be difficult to prove and its terms may not be clear. A physician who operates on the basis of an oral consent should, where possible, have at least one disinterested witness present when the consent is given, to minimize problems of proof.

Written consents can obviate many of the problems in connection with implied and oral consents—particularly the problems of proving the fact of consent and the terms of the consent. However, written consents should not be regarded as a panacea for all problems of the physician. For example, if a physician or a hospital follows the practice of requiring written consents before an operation and if the physician or hospital decides in a particular case not to require a written consent but to rely upon an oral consent and if the patient should later deny that he had given his oral consent, a court would probably admit in evidence testimony showing the existence of such a practice and such testimony could then be considered by the jury as evidence supporting the patient's testimony that no oral consent had been given. This problem could be minimized if the policy of the physician or hospital were not to require written consents in every case but rather to require written consents in such cases as they deem appropriate.

As a result of the foregoing we are of the opinion that written consents are undoubtedly the safest method of procedure for both a physician and a hospital to follow. However, we are further of the opinion that neither a physician nor a hospital should adopt a policy that no operation may be performed without a written consent because of the unfavorable repercussions of such a policy in cases where written consents are not obtained through inadvertence or otherwise.

We have examined forms of written consents used by several hospitals. From our examination of these forms we are of the opinion that many of them leave much to be desired. For example, one form attempts to relieve the physician and the hospital from liability for malpractice. We doubt whether such a written consent, even if properly signed, would be held by a court to be binding. Another form authorizes "whatever operation may be necessary or advisable." It does not, however, state who is to determine whether the operation is necessary or advisable. We fear that if litigation arose with respect to such a form, a court would say that the question of whether the operation was necessary or advisable is one to be decided by the jury. We would, therefore, recommend that such form be revised so as to authorize whatever operation may, in the opinion of the physician or surgeon in charge, be necessary or advisable. Many of the forms authorize whatever anesthetics are necessary. We would also recommend that this phraseology be revised so as to make clear who is to determine what anesthetics are necessary.

President's Letter

MEDICARE

Although your immediate past president, Dr. R. H. Wilson, discussed "Dependent Medical Care" in his October and December letters, this problem seems important enough, now that the law is in effect, to warrant additional consideration of its origin and of the possible effects of the statute on the physicians of Minnesota.

Under the terms of this law, the wives and children of members of the uniformed services henceforward will be able to obtain medical care without financial obligation to themselves. The term "uniformed services" includes the Army, Navy, Air Force, Marines, Coast Guard, and the commissioned corps of both the United States Public Health Service and the Coast and Geodetic Survey. The arrangement by which this will be done is known as "Medicare." Certainly, it is of interest to the physicians of the State of Minnesota to know something about the background and chronologic developments of the Medicare program.

In December, 1954, the House of Delegates of the American Medical Association voted that "if it is to be the policy of the Government to provide medical care for dependents of Service personnel, the services of civilian physicians and hospitals should be used whenever possible, to be paid for at prevailing rates with provision for free choice of physicians."

On June 11, 1956, the House of Delegates of the American Medical Association adopted a resolution in which it was urged that all medical associations co-operate with the Department of Defense "in the provision of medical service to the dependents of Service men, utilizing such insurance, medical service, or health plan or plans as are encompassed by the law. A plan or program for any given geographical area should first be approved by the organized medical profession of that area." At the same time, the House of Delegates also directed the Board of Trustees "to initiate direct liaison with the Department of Defense and render all reasonable and effective aid and assistance to State and County medical societies toward implementation of the Act."

Next, a special task force to study the problem of the medical care of dependents of service men was set up by the Board of Trustees of the American Medical Association. This task force engaged in a series of conferences with the Department of Defense. On July 28 and 29, 1956, representatives of constituent medical associations were called into conference by the American Medical Association in Chicago for discussion of the Medicare program with representatives of the Department of Defense. The task force and its special Committee have maintained continuous contact with the appropriate committees of the uniformed services in an effort to promote the best possible implementation of the Dependents' Medical Care Act.

The North Central Conference, consisting of Minnesota, Wisconsin, Nebraska, Iowa, and North and South Dakota, met in St. Paul in special session with representatives of the Department of Defense on Saturday and Sunday, August 11 and 12, 1956. Representatives of Ohio, Arkansas and Washington also attended the Conference, and the representatives of those three states expressed wholehearted, unanimous support of and co-operation with members of the North Central Conference in the Dependents' Medical Care program.

It seems obvious that the program for the medical care of dependents of military people actually is but one facet of a large and acute personal problem which vitally affects the security and financial well-being of the United States. In fact, civilian medical care for dependents who do not have access to military hospitals

is but one of a number of steps taken to increase the appeal for medical care for the military and dependents. And so, at the regular annual meeting of the North Central Medical Conference on Sunday, November 11, 1956, the Conference resolved "that the North Central Medical Conference recommends to the delegates and trustees of the American Medical Association that they continue to urge upon legislative bodies and the Department of Defense the great advantage of an additional allotment to the service man for the purpose of paying for the medical care of his dependents as a course which will improve the service man's morale and make more attractive to him a permanent career with the armed forces." It was felt that this allotment plan might remove the necessity for drafting civilian physicians into the armed forces for the purpose of providing medical care for the dependents of service personnel.

Minnesota and the other north central states immediately undertook active planning for the program for medical care. As a result, Mr. R. R. Rosell, our executive secretary, and Mr. Jules Hannaford, our legal counsel, went to Washington to negotiate a contract for the performance of various medical and surgical procedures employed in the practice of medicine. Thus, as in many previous endeavors of which the objectives were improvement of the health of our people, Minnesota medicine again has been in the forefront of this large and important undertaking.

The Council of the Minnesota State Medical Association has reviewed and revised the program in some areas. Finally, the contract was signed by the Department of Defense and duly appointed representatives of Minnesota medicine, and physicians of the State of Minnesota by law are now required to minister to the wives and children of men in uniform on a fee-for-service basis.

An advisory committee of Minnesota physicians will assist the executive secretary, Mr. Rosell, in trying to prevent inequities in the payment of fees and in adjudicating any misunderstandings and misconceptions arising from the practical operation of this program.

Hence, the burden of making this plan succeed rests upon the physicians of Minnesota and the people generally. Professional charges must be fair and in agreement with prevailing charges for a given procedure, in a given geographic region.

Let no one be misled by the thought that Medicare is a "final plan." Changes in it can be made at will by the Federal Government, and by the Department of Defense in particular.

Any physician who cares for patients eligible for Medicare should remember:

1. Medicare is intended to provide *full payment* for all services covered.
2. Medicare does not apply to normal outpatient care, with these exceptions:
 - (a) The cost of examinations that lead to immediate hospital care is covered up to \$75.00.
 - (b) The cost of treatment required after accidents is covered from \$15.00 to \$90.00. The first \$15.00 is the patient's responsibility and any sum in excess of \$90.00 likewise is the patient's responsibility.
 - (c) The cost of prenatal and postnatal care is provided.
3. Medicare pays for semiprivate accommodations in the hospital. The cost of private accommodations is covered by this plan only when the attending physician certifies that such accommodations are necessary.

A large, stylized handwritten signature in dark ink, appearing to read "J. M. Bergen". The signature is fluid and cursive, with a large loop at the end.

George Earl, M.D., Chairman

85th CONGRESS GETS UNDERWAY WITH RECORD NUMBER OF BILLS INTRODUCED

The 85th, Democratic-controlled Congress is underway with a record number of bills introduced in the House on opening day. Experience has shown that about three per cent of all bills are found to be of major importance to medicine. As Congress opened, the Eisenhower administration, through HEW Secretary Folsum, announced part of its medical-welfare program for this year. Beyond much question, the new Congress, like the last one, will be anxious to vote large sums of money for existing programs, particularly research, and to set up new programs in the health and medical fields. This Congress probably will not be afraid of spending money or of starting health-medical programs that might be considered experimental.

However, because of the probable bi-partisan demands for a step-up in military and foreign spending, there cannot be unlimited military and foreign aid dollars and, at the same time, unlimited health-medical dollars.

As usual, a majority of the health bills won't even be considered seriously by the committees. Some will be the subject of hearings, but not reported out of committee. A few will move on to enactment. All bills not enacted or actually defeated, however, will hold over through 1958 and can be picked up at exactly the point they had reached at adjournment of the 1957 session.

Health and medical legislation which will probably receive the most serious consideration in this session includes:

Construction Grants for Medical Schools

The Administration is again asking Congress to authorize construction grants for medical, dental, public health and osteopathic schools. The money would be used to help pay for facilities for more students rather than for salaries of teachers or for maintenance costs.

Federal Workers' Health Insurance

The goal here is to produce a "package" bill with both basic and catastrophic coverage—one

that will meet the approval of the nonprofit plans, the commercial carriers and the federal employees unions. Two previous proposals—one for basic and the other for catastrophic coverage—have failed to pass because of objections of one or more groups to some aspect of the plans.

Voluntary Health Insurance

Both the Administration and the Democrats are working on ways to bring about more rapid expansion of health insurance. The Administration's reinsurance plan, twice rejected by Congress, remains in the background. Coming to the fore this year is a substitute plan which would permit smaller insurance companies to pool their resources without violating antitrust laws. It is felt this would stimulate coverage for major medical expenses for farmers, for the aged and for low-income families.

Tax Deferment on Retirement Plans

Interest has been renewed in the Jenkins-Keogh plan for permitting the self-employed to defer payment of taxes on money paid into retirement plans. Supporters of the proposal (including the American Bar Association and the AMA) point out that enactment of the plan would place professional groups on a par with employed persons. The cost of this proposal will be one of the points on which it will be vigorously attacked.

Regular Draft Amendment for Physicians

The six-year-old doctor-draft act expires July 1, 1957, and, barring any new emergency, the Defense Department says it will not ask Congress to extend it. In its stead, the Defense Department plans to ask for an amendment to the regular draft to provide for the selective call-up of doctors under the age of thirty-five who have been deferred to complete their educations. These groups have an obligation under their regular draft for two years of service unless excepted for specific reasons. Meanwhile, to encourage young doctors to take their military training after leaving medical school and possibly elect to make military-medicine a lifetime career, the services are sponsoring intern

and residency training programs. Under this special deferment plan, doctors promise active service at a later date.

Additional Social Security Amendments

If Congress runs true to form, there will be an abundance of bills designed to liberalize the much-amended Social Security Act. There will be demands for lowering the age for disability cash payments for temporary disability, for hospitalization of those over sixty-five who are eligible for current old age benefits and, to help finance these and other plans, a higher ceiling on earnings subject to social security tax.

With reference to the "payments to the disabled" amendment, the Social Security Administration is considering a recommendation from the Indiana State Medical Association to establish district or county committees of physicians to review individual doctors' medical findings under the new law providing O.A.S.I. payments to the disabled at age fifty. The committee would review the physician's report, further examine the applicant if so desired, and be authorized to file the final report of impairment determination and make recommendations as to whether the report might be reversible by medical or other rehabilitative measures. A similar recommendation is under study by the AMA Board of Trustees.

Federal Aid to the Aged

With Secretary Folsom heading the new Federal Council on Aging, it is expected that the Eisenhower Administration will put forth new efforts to help solve some of the social problems of the aged. In Congress, Senators Hill and Kennedy are expected to press for their bill which authorizes federal grants to states.

Appropriations for Health

In all likelihood, Congress will be asked to appropriate at least the same amount voted last year. In the Department of HEW, for example, Congress in 1956 approved over \$772 million for health programs.

Miscellaneous Legislation

Other measures bearing on the medical profession which will again come up in the 85th Congress include the Poliomyelitis Vaccine Grants Act, the Bricker Amendment, Federal Aid to Local Public Health Units and Nursing School Aid.

PERSONNEL CHANGES IN NEW DEPARTMENT

Marion B. Folsom stays on in his Cabinet post as Secretary of the Department of Health, Education and Welfare, but he will have several new top level aides.

Dr. Herold C. Hunt, HEW undersecretary, resigned in January to return as Eliot professor of educational administration at Harvard University. Dr. Lowell T. Coggeshall, special assistant for health and medical affairs, left to return to the University of Chicago, and Roswell B. Perkins, HEW assistant secretary, left in November to return to a New York law firm. He was responsible for developing HEW's legislative program and policies on Social Security matters.

Dr. Aims C. McGuinness will replace Dr. Coggeshall and Elliot Richards will replace Perkins. Dr. McGuinness is the former dean of the University of Pennsylvania Graduate School of Medicine and Richards is a thirty-six-year-old Boston attorney.

AIRCADE TEAM TO TAKE LEGISLATIVE ISSUES TO CITIES

The Chamber of Commerce of the United States has launched a unique legislative project of interest to physicians. A National Chamber team of experts spent all of February taking national issues directly to businessmen and professional people to spur them on to more intensive action. This "Aircade," which had Minneapolis on its schedule for February 11, will discuss many issues which affect medicine: Hoover Commission recommendations, government in the health insurance business, social security, government spending and taxes.

HEALTH GROUPS ASKED TO AID HUNGARIAN MEDICAL PERSONNEL

With more and more Hungarian physicians entering this country, the World Medical Association and the Health Resources Advisory Committee of the Office of Defense Mobilization in Washington has asked all American doctors to do everything possible to help these men and women who have fled from their homeland. This Advisory Committee adopted a resolution urging "every American health organization and educational institution to make every effort to lend its aid and resources toward the re-establishment of our new professional colleagues in situations com-

mensurate with their professional status. . . . To the dignity of political and personal freedom, let us help give them the dignity of professional status."

The A.M.A. has asked that county medical societies ascertain whether any Hungarian physicians have come into their communities and, if so, to plan some program for them so that their professional talents will be utilized in the most effective way possible.

TWENTY-FOUR PHYSICIANS RECEIVE SEARS-ROEBUCK GRANTS

Assistance in the form of long-term, unsecured loans to twenty-four physicians for the establishment and improvement of fifteen medical practice units has been announced by the Sears-Roebuck Foundation. The fifteen loans go to physicians in Oregon, Washington, Southeastern Kentucky, Minnesota, California, Mississippi, Georgia, North and South Carolina, southern Florida, New York, Rhode Island and Connecticut. Purpose of the plan is to help physicians supplement personal and local financing which is inadequate to cover the entire cost of building, remodeling, equipping or establishing a medical practice.

PHYSICIANS REMINDED OF PROFESSIONAL TAX DEDUCTIONS

When physicians figure their deductions for professional expenses on the Federal income tax return, most of them concentrate on the big items like salaries, depreciation and rent. But there are twenty-seven other varieties of business deductions most physicians are entitled to: They are: *Accounting* (amounts paid for bookkeeping services); *Automobile* (full operating cost of your car if used only for professional calls); *Bad debts*; *Clubs* (dues and expenses if necessary for maintaining business or professional contacts); *Collection expenses*; *Conventions* (cost of attending out-of-town medical meetings); *Credit Bureau fees*; *Depreciation* on all professional property; *Entertainment* (if necessary to practice); *Equipment*; *Gifts* (if necessary to practice); *Insurance* (premiums on policies related to your profession); *Interest* (on practice-connected loans and mortgages); *Journals and Books*; *Litigation expenses*; *Licenses*; *Loss* (from theft or damage or business property); *Maintenance* (if connected to office upkeep); *Medical Society Dues*; *Moving* (if connected with practice); *Refresher Courses*; *Rent*; *Repairs to*

office; *Salaries*; *Medical and Office Supplies*; *Taxes*; *Telephone and Telegraph*; *Travel*; and *Uniforms*.

There are also income tax deductions for volunteer work done for charitable organizations. You may not take a deduction for the value of the time you give but can count as a contribution any out-of-pocket expenses, that are directly connected with your volunteer activities (travel costs, costs of uniforms, et cetera).

Also keep in mind deductions allowed on your income tax for contributions to charity and your church and there are additional tax breaks on gifts of property or securities.

There is bad news for some taxpayers, however, in official proposals being readied for action in congress. These plans call for the closing of many favorite loopholes used by taxpayers for years. For example, stockholders in community-property states may lose some highly important tax advantages as may retired couples in those same states. The wealthy and moderately well-to-do men who have been piling up life insurance to pay their estate taxes may be due for a setback. Investors in some types of bonds may find a loophole tightly closed. Also taxpayers who have been enjoying double benefits on some deals may see these practices prohibited. The official plan is to close most of these loopholes retroactively, applying new amendments to much or all of 1956.

SURVEY REPORTS ON PHYSICIANS

Physician-Death Census

A study of all physician deaths between 1949-51 showed that there were six per cent fewer deaths among them than would have been expected among other white adult males. However, heart disease and diabetes hit physicians harder than other men.

Life expectancy for the medical profession was better at almost every age level than it was for other men.

Satisfaction With Career

If a doctor had his life to live over, would he choose medicine as his career? Ninety per cent of the physicians asked this question answered, "yes." In answer to the question, "Would you select your particular field of medicine?" 85 per cent of the psychiatrists answered yes; 82 per cent

(Continued on Page 140)

PARTICIPATION OF PHYSICIANS IN PRIVATE PRACTICE IN BASIC TUBERCULOSIS CONTROL PROCEDURES

Prevention

1. Phases of program in which physicians can participate in a professional capacity.

(a) It is the responsibility of all physicians not only to inform his own patients and their families about the dangers of tuberculosis, its mode of spread and methods of control, but also to assist in preparing the disseminating informational material to the public in co-operation with the health department, tuberculosis associations, and other agencies interested in control and treatment of tuberculosis.

- (b) Early casefindings and diagnosis:

(1) The doctor's office is a productive site for casefindings. The physician should consider the possibility of tuberculosis in every patient and examine as many as possible by roentgenologic study, especially those with any suspicious signs or symptoms or with history of exposure to tuberculosis, x-ray, tuberculin tests and bacteriological examination should be used as freely as possible.

(2) Physicians should examine all the contacts of their tuberculous patients to find the source of the disease and to detect its spread to others; or should make sure that they are examined by public health department or other clinics. Tuberculin tests and x-ray films should be used.

(3) All physicians should encourage their hospitals to establish a program of routine hospital admission x-rays; if such a program is in effect, to promote its fullest use. As far as admission and periodic chest x-ray films in mental and other institutions are concerned, physicians can influence the responsible operating agencies to institute such programs.

(4) Those physicians who sit on policy making committees should direct surveys to high prevalence areas.

(5) Private physicians should welcome and support community x-ray surveys; they should participate in them as pol-

icy makers; each physician should make certain that suspects screened out by the survey are examined carefully using all the appropriate diagnostic tools; he should sit in on film reading sessions.

(6) As consultants or board members for mental and penal institutions or as staff physicians, should promote routine and periodic chest x-raying in such institutions, as well as routine x-raying in jails.

(7) Physicians should support and use laboratory services as needed and especially in doubtful tuberculosis cases. Accepted laboratory techniques, particularly culture and guinea pig inoculation examinations should be used since one should not rely on direct smears.

(c) It is the duty of all physicians to do everything possible to hospitalize every open case of tuberculosis. If beds are not available, patients should be adequately isolated and treated at home. It is also the physician's responsibility to see that the patient remains under treatment for a period of time sufficient to reduce the possibility of relapse to a minimum.

(d) BCG vaccination of physicians, medical students, nurses, laboratory workers, contacts and others in the more vulnerable groups, who as non-reactors are exposed to tubercle bacilli, should be left to the discretion of the individual physician in the individual case.

2. Phases of the program in which physicians can actively co-operate with others in community projects.

(a) Private physicians should refer patients and families to health departments and other health agencies for bedside nursing care, assistance in isolation practices, epidemiologic investigations and family education.

(b) The private physician should refer tuberculous patients and their families to social services and public assistance agencies when necessary.

(c) Physicians, as citizens, can actively participate in community projects aimed at

slum clearance, low cost housing projects and other movements aimed at general betterment of the community.

(d) The practicing physician should emphasize the importance of pasteurization of milk and milk products, and should support the tuberculin testing program for eradication of tuberculous cattle.

B. *Treatment and Follow-up*

1. Private physicians have always played and will continue to play a prominent role in the treatment of tuberculosis. While government sanatoria care for the majority of hospitalized tuberculous, many chest physicians, internists, and other specialists, are on consultant staffs and play a dominant role in setting treatment policies.
2. In the absence of sanatorium or hospital beds, medical care of tuberculous patients at home is largely in the hands of private physicians. Organized home care programs are operating in many communities in which private physicians should actively participate; they should make certain that patients receive necessary nursing and other services to aid in carrying out medical recommendations.
3. The new drugs have increased the number of tuberculous patients who are eligible for post-sanatorium ambulatory treatment. A large number of these are under the supervision of either private physicians or public clinics.
4. Physicians should perform and stimulate regular follow-up examination of tuberculous patients in the doctor's office or chest clinics. Physicians in private practice often serve part-time in tuberculosis or chest clinics, and all physicians should encourage good clinic service. Private physicians should welcome the help of public health nurses with patients' families and contacts to keep them under medical supervision and increase their understanding of the disease and its spread. In some communities medical social workers are available and can visit patients with social problems. Occasionally voluntary associations employ occupational therapists who can be of assistance to patients in their homes.
5. Ideally, no diagnosed case of tuberculosis should ever be dropped from periodic examination. However, after tuberculosis patients have been inactive for two years close supervision can be relaxed. Physicians

should, nevertheless, advise their patient with inactive disease to have an annual examination including an x-ray film.

C. *Reporting*

1. Physicians should routinely and promptly make out morbidity cards on cases of tuberculosis which come to their attention. If there is any doubt about a previous report being made, the physician should make one out anyhow to assure the completeness of registration and epidemiological follow-up. Death certificates should not only indicate tuberculosis as an immediate or ultimate cause of death, but also as an accompanying condition when present.
2. Private physicians should provide health departments with information about the current status of tuberculosis patients under their care so that continued knowledge and supervision of all cases of tuberculosis in the community is assured.

D. *Provision to the patient of indicated ancillary services*

1. It is the responsibility of the private physician to assess the patient's capacity for work in terms of residual disease in the lung and/or other organs and determine the amount and types of activity permissible for the individual. He must make decision as to whether or not the patient can return to his former occupation or whether he should return to one requiring less physical exertion. In this decision as in those relating to diagnosis and treatment he can to advantage avail himself of specialist consultation.
2. When it is evident that the patient is in need of vocational training to equip him to enter a new occupation, the physician should be aware of the facilities available for such training. He can call upon the services of the vocational counselor of the Division of Vocational Rehabilitation in his State or territory to assist him.

International Congress of Electroencephalography and Clinical Neurophysiology, Brussels, Belgium, July 21-28. Dr. R. G. Bickford, Mayo Clinic, Rochester, Minnesota.

International Congress of International Society of Bronchoesophagology, Philadelphia, Pennsylvania, May 12-13. Dr. Chevalier L. Jackson, 3401 North Broad Street, Philadelphia.

International Congress on Medicine and Surgery, Turin, Italy, June 1-9. Secretariat, Minerva Medica, Corso Bramante 83-85, Turin, Italy.

International Congress of Neurological Sciences, Brussels, Belgium, July 21-28. Dr. Pearce Bailey, National Institutes of Health, Bethesda 14, Maryland.

International Congress of Neurosurgery, Brussels, Belgium, July 21-28. Dr. William B. Scoville, 85 Jefferson Street, Hartford, Connecticut.

International Congress of Neuropathology, Brussels, Belgium, July 21-28. Dr. Ludo J. Bogaert, 47 rue de l'Harmonie, Antwerp, Belgium.

International Congress of Nutrition, Paris, France, July 24-29. Congress International de Nutrition, 71 Blvd. Pereire, Paris 17e, France.

International Congress of Otolaryngology, Washington, D. C., May 5-10. Dr. Paul H. Molinger, 700 North Michigan Avenue, Chicago 11, Illinois.

International Congress on Rheumatic Diseases, Toronto, Ontario, Canada, June 23-28. International Congress on Rheumatic Diseases, P.O. Box 237, Terminal "A," Toronto, Ontario.

International Gerontological Congress, Merano-Bolzano, Italy, July 14-19. Segreteria, Quarto Congresso Internazionale de Gerontologia, Viale Morgagni, 85, Firenze, Italy.

International League Against Epilepsy, Brussels, Belgium, July 21-28. Dr. Radermecker, Institut Bunge, 59 rue Philippe Milliot, Berchem, Antwerp, Belgium.

International Symposium on Medical-Social Aspects of Senile Nervous Diseases, Venice, Italy, July 20-21. Secretariate, Viale Morgagni 85, Firenze, Italy.

International Voice Conference (Laryngeal Research Function and Therapy), Chicago, Illinois, May 20-22. Dr. Hans von Leden, 30 North Michigan Avenue, Chicago 2, Illinois.

Neuroradiologic Symposium, Brussels, Belgium, July 21-28. Professor Melot, Hôpital Universitaire St. Pierre, Brussels, Belgium.

Pan-Pacific Surgical Association, seventh congress, Honolulu, Hawaii, November 14-22, 1957. Write Dr. F. J. Pinkerton, director-general of the Pan-Pacific Surgical Association, Room 230, Young Building. Honolulu, Hawaii.

AMERICAN COLLEGE OF SURGEONS TO HOLD SECTIONAL MEETING IN SAINT PAUL

A Sectional Meeting of the American College of Surgeons will be held at the Lowry and Saint Paul Hotels in St. Paul, April 8-10, 1957. Dr. Charles E. Rea is chairman of the committee arranging for this meeting for surgeons in the north central states.

Papers will be presented on such subjects as Hazards of Blood Transfusions, Treatment of Massive Upper Gastrointestinal Tract Hemorrhages, Whiplash Injuries, Prevention of Injuries, Hemorrhagic Diseases Related to Surgery, Fracture of the Larynx, Inguinal and Femoral Hernioplasty, Megacolon in Infants and Children, Tendon Injuries in the Hand, and Prostheses for Amputees.

Symposia have been arranged on What's New in Surgery, Orthodox Versus Newer Concepts in Treatment of Breast Cancer, Care of Patients with Gastrotomy, Ileostomy or Colostomy, Where to Begin and What to Do for Patients with Multiple Injuries, and Peripheral Vascular Surgery. Panel discussions will be held on Conservation of Ovarian Tissue and Biliary Tract Surgery.

There will be a separate program for specialists in ophthalmic surgery, including a symposium on Industrial Ophthalmology.

Fellows, members of the candidate group, interns and residents may attend this session free of charge, but there will be a \$5.00 registration fee for non-fellows.

BLUE SHIELD MEETS NEW CHALLENGES

(Continued from Page 130)

other Plans have promised to "go along" in the near future.

While this degree of co-ordination of benefits (in terms of covered services) has been found necessary to meet Blue Shield's enrollment challenge, each Plan will still make payments to physicians according to its locally negotiated schedules, and will calculate its own subscription rates.

This significant achievement of Blue Shield shows its ability to meet new conditions and proves the capacity of medicine's voluntary prepayment movement to solve whatever problems it may encounter.

SURVEY REPORTS ON PHYSICIANS

(Continued from Page 136)

of the internists; 81 per cent of the surgeons; 78 per cent of the obstetricians; 66 per cent of the G. P.'s and 63 per cent of the pediatricians.

Attendance at Medical Meetings

According to a recent survey, 50 per cent of the doctors questioned, attend "most meetings" of their local or county society. The problem of meeting attendance seemed greatest in the East where only 38 per cent said they attended most meetings while in the West the percentage increased to sixty-one.

FOR A "DRY" CARDIAC PATIENT...

The glomerulus is invested in the lamina densa which is continuous with the basement membranes of the outer capsular epithelium.

Illustration by Hans Elias

Rolicton® Diuresis Maintains Continuous Edema Control

The efficacy of Rolicton (brand of amisolmetradine) in maintaining diuresis in the edematous patient has been established on an average dosage of one tablet b.i.d. Larger doses may be given as initial therapy and as maintenance therapy in edema difficult to control. Many patients will respond to one tablet daily.

"The margin of safety and the diuretic index is certainly an improvement over the use of oral mercurial diuretics."¹

Avoiding "Peaks and Valleys"

A highly desirable effect, and one which has been made possible with Rolicton, is the maintenance of continuous diuretic effectiveness day after day over an extended period, to avoid the up-and-down weight pattern typical of other edema-control methods.

"There was an obvious stabilization of weight in practically all of the patients under observation, and previous wide fluctuations in poundage disappeared."²

Mercury-Sparing

Typical of the Rolicton diuresis pattern is the ability of the drug to reduce and, in a large percentage of patients, to eliminate the need for mercurials parenterally.

"... the drug represents a most useful addition to our armamentarium in the treatment of edema, not only because it can be given orally ... but more so because it permits [us] to replace or to spare the ... mercurials."³

SEARLE

Woman's Auxiliary

AMA AUXILIARY CAMPAIGN AGAINST CANCER

Members of the Woman's Auxiliary to the American Medical Association throughout the country have adopted a plan for an intensive education campaign against cancer, as announced by the American Cancer Society and the Woman's Auxiliary to the American Medical Association. An especially prepared Cancer Education Program Kit, currently being sent to all American Medical Association Auxiliaries, will serve as guides for program building for these all-important leaders.

In announcing the plans for the co-operative venture, Mrs. John H. Cameron, Crookston, Cancer Chairman for the Minnesota State Medical Association Auxiliary, said: "We have come to know by bitter experience what a devastating disease such as cancer can do to victim and family alike. When a home has been broken because of a needless death, the tragedy is all the greater. Therefore, we are eager to do all we can to educate ourselves and our friends with the Society's life-saving message."

Allan Stone, Executive Director, Minnesota Division, American Cancer Society, expressed gratitude for this co-operation and pointed out the startling number of lives lost because proper treatment was begun too late—80,000 Americans last year. "Anything which the Woman's Auxiliary to the American Medical Association can do to aid in reducing this dreadful toll will be of lasting effect in the total cancer picture," he said.

STATE CHAIRMEN OUTLINE 1957 PROJECTS Cancer

Another Auxiliary work year is at hand and it is indeed gratifying that so many units have appointed cancer chairmen who will be able to devote more time to this important project and to whom we might channel information directly.

Through the efforts of Allan Stone, executive director of the Minnesota Division, American Cancer Society, Inc., cancer chairmen have received copies of the cancer education kits for the Auxiliary. Local chairmen are asked to study these carefully and then outline their group's participation on as large a scale as possible, particularly in education. The Cancer Society will also help make arrangements for speakers for programs.

Suggested reading in this field is the Minnesota Cancer Committee's report. "Minnesota Doctors Are Beginning to Detect Occult Cancer," found on page 746, November, 1956, issue of MINNESOTA MEDICINE. This should arouse and convince everyone of the urgency of 100 per cent participation in the cancer crusade and, as stated by the Cancer Committee, "the benefits from co-operative statewide effort will be incalculable."

MRS. J. H. CAMERON, Crookston
State Auxiliary Cancer Chairman

Mental Health

Mental Health Week, which takes place the last week in April, will soon be here, and we urge all our Auxiliary groups to make plans for some type of program. There are many things one can do to help the mentally-ill, depending on the locality. If you are near a mental hospital, orphanage or a home for the aged, anything you can do to help make the patients happy is always appreciated. Mental Health involves so many things besides the mentally ill, however. What we would like to do is to educate our people so they have happier lives and are therefore mentally strong.

We would like to start our high schools using the "Milestones to Marriage" series. This is a very well-written series of letters to high school seniors. The means of financing such a project is always a problem but these groups have been found willing to help: the Mental Health Association, city or county boards of education, local high school funds, student projects, P.T.A., Kiwanis, Rotary, Lions, or Chamber of Commerce groups, foundations, individuals, et cetera.

We ask all Auxiliary groups to use to the best advantage the material sent them on mental health.

MRS. W. P. GJERDE, Lake City
*State Auxiliary Mental
Health Chairman*

Science Fairs

Again this year the AMA will award citations to top scientific youth at the 1957 National Science Fair in Los Angeles, May 9-11. In addition, the two first-place winners will be invited to exhibit their projects at the 106th annual AMA meeting in New York City June 3-7. Participation of state and county groups in last year's fairs brought a great deal of favorable public comment and proved to be a very successful venture in youth guidance and community relations.

The Minnesota State Medical Association has endorsed the support of local fairs by state and county medical societies, and encourages the Auxiliary to adopt this as a worthy project.

A science fair is an exhibition of scientific projects prepared by elementary and high school students for showing to their classmates, teachers, parents and the public. Local winners go on to compete in regional science fairs and then on to the national science fair where the AMA presents its special awards.

Groups interested in this very worthwhile project may check with local high school science instructors and principals for possible sponsorship of a fair. For further information on how to organize these fairs, you may write to Science Clubs of America, 1719 N Street N.W., Washington 6, D. C. Almost all fairs are concluded by late April so the winners may prepare for the national competition.

Pheneen®

ULMER

ELIMINATES DOUBTFUL STERILITY
IN OFFICE USE . . .

Rapid germicidal activity plus specific sporacidal properties enable PHENEEN to provide the extra margin of safety during minor office surgery. Instruments may be stored for months in PHENEEN without weekly changes of solution.

Special "built-in" rust inhibitor makes this possible. Routine use of colorless, odorless PHENEEN reduces questionable sterility to the minimum. For complete information and prices write . . . MM-257b.

STATE CHAIRMEN OUTLINE

(Continued from Page A-38)

Every group participating in these fairs is performing an outstanding service, because the continued success of our industries and professions depends on an adequate supply of scientists and technologists. Also, the program serves a fine "career-counseling" purpose for youth and is an excellent anti-delinquency program.

MRS. PHILIP K. ARZT, St. Paul
State Auxiliary Program and
Health Education Chairman

NEWS FROM THE COUNTY AUXILIARIES Red River Valley

The Woman's Auxiliary to the Red River Valley Medical Society held a joint dinner meeting with their husbands December 7, 1956, at Sidney's Cafe in Crookston. Following the dinner the women adjourned to the home of Dr. and Mrs. A. R. Reff for their meeting.

Renville-Redwood

Dr. and Mrs. G. E. Nelson and Dr. and Mrs. J. F. Haas, Fairfax, were hosts to the Renville-Redwood Medical Society and its Auxiliary at the Nelson home Thursday, December 20. A turkey dinner was served by the hostesses. Instead of exchanging gifts the collection taken was used for an educational fund. Following dinner, the Auxiliary had a short meeting. Mrs. A. W. Diessner, Redwood Falls, is the new president of the group.

St. Louis County

The Auxiliary met Tuesday, January 8, for a 1:00 p.m. luncheon at the Duluth Athletic Club. Note author Margaret Culkin Banning was guest speaker.

Winona County

The Winona County Auxiliary celebrated the holiday with a luncheon at the home of Mrs. W. O. Finkelnburg, Winona. During the business session the group voted that a sum of \$25.00 be donated to Hungaria relief.

* * *

Contributions for this column, including news and activities of state auxiliary societies and items of interest about members, may be sent to Mrs. A. B. Rosenfield, Woman's Editor, MINNESOTA MEDICINE, 2920 Dea Boulevard, Minneapolis, Minnesota.

It is generally accepted that tuberculosis is the most common cause of pulmonary cavitation. The tuberculosis is a frequent occurrence in third-stage silicosis is evident when one considers that over 50 percent of the conglomerate masses are said to be infected with tuberculosis. Thus, when cavitation occurs in conglomerate mass, it is usually presumed to be of tuberculous nature. However, the occurrence of non-tuberculous cavitation must not be overlooked.—C. S. MORROW, M.B., and R. N. ARMEN, M.D., *Annals of Internal Med.*, Oct., 1956.

In Memoriam

JEAN T. LAPIERRE

Dr. Jean T. Lapierre, Minneapolis, died December 25, 1956. He was fifty-eight years old.

A life-long Minneapolis resident, Dr. Lapierre attended St. Thomas College, St. Paul, and graduated from Creighton Medical School, Omaha, in 1924. He was a fellow of the American College of Surgeons, a staff member of St. Mary's Hospital, Minneapolis, and a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association.

He also belonged to the Minneapolis Athletic Club, Interlachen Club, St. Anthony Commercial Club and the Foresters.

Survivors include two sisters: Mrs. Esther Barry, St. Paul, and Mrs. E. W. Beauchamp, Springfield, Mass., and two brothers, Dr. Arthur Lapierre and Dr. Maurice Lapierre, both of Minneapolis.

FREDERICK J. PLONDKE

Dr. Frederick J. Plondke, founder and long-time medical director of St. John's Hospital, St. Paul, died here January 2, 1957. He was eighty-seven years old.

Dr. Plondke was the first graduate of Morningside College, Sioux City, Iowa, where he received a Bachelor of Science degree in 1894. In 1898 he received his medical degree from the University of Pennsylvania and the following year set up practice in St. Paul. He founded St. John's Hospital in 1911 and served as medical director for forty years and as chief of staff for more than thirty years. Upon his retirement in 1955 he was given the title of honorary chief of the surgical service and continued as a member of the governing board of the hospital.

A member of the staff of Hamline University, Dr. Plondke was professor of histology from 1901 to 1903 and later was professor of clinical pathology. He was also pathologist at Ancker Hospital.

Dr. Plondke was a major in the Minnesota National Guard and headed medical units during the Moose Lake and Cloquet fires. He was a past-president of the Ramsey County Medical Society, a member of the Minnesota State Medical Association, the American Medical Association, the Shrine and the Evangelical and Reformed Church.

His wife, the former Madeline May Bruchman, survives.

The ancient art and the burgeoning science of medicine know no national or racial distinctions. Medicine, like art and music, speaks with a human tongue, and its knowledge and techniques are dedicated to all mankind. Ed. *World Med. J.*, May, 1956.

General Interest

Dr. George R. McNear, Jr., Mankato, has been elected president of the Blue Earth County Medical Society for the coming year. Dr. E. E. Heller and Dr. Donald B. Swenson, both of Mankato, were elected vice-president and secretary-treasurer, respectively.

* * *

Dr. J. C. Feuling, Duluth, is the newly-elected president of the St. Louis County Medical Society for 1958. Installed as president for 1957 at the December meeting of the Society was Dr. E. E. Barrett. Retiring president was Dr. A. J. Bianco. Both are from Duluth. Dr. R. E. Hansen, Hibbing, is vice-president; Dr. R. O. Bergen, Duluth, secretary-treasurer. Elected to the advisory committee for the next three years were Dr. K. E. Johnson, for 1957; Dr. A. L. Abraham, for 1958, both of Duluth, and Dr. K. L. Butler, for 1959, Cloquet.

Other physicians voted into office include Drs. A. G. Athens, M. F. Fellows, both of Duluth, and L. W. Johnson, Hibbing, state advisory committee; Drs. P. N. Bray, J. E. Haavik, G. C. MacRae, O. L. McHaffie, all of Duluth, and W. S. Neff, Virginia, nominating committee.

Judiciary committee: Drs. A. G. Athens, G. C. MacRae and D. W. Wheeler, all of Duluth, 1957; Drs. P. N. Bray, C. O. Kohlbray, and Archie Olson, all of Duluth, 1958, and Drs. M. G. Gillespie, P. S. Rudie, both of Duluth, and Clarence Jacobson, Chisholm, 1959.

Economics Committee: Drs. M. G. Fredricks, H. O. Hoff and O. E. Sarff, all of Duluth, 1957; Drs. Walter Kelley, William Martin, both of Duluth, and K. E. Ahola, Hibbing, 1958; and Drs. C. M. Bagley, J. J. Coll, both of Duluth, and R. H. Puumala, Cloquet, 1959.

Grievance committee: Drs. Feuling and M. J. McKenna, Grand Rapids, 1957; Drs. L. L. Merriman and J. H. Peterson, Duluth, 1958; and Drs. McHaffie and D. W. Wheeler, Duluth, 1959.

Delegates: Drs. R. P. Buckley and McHaffie, 1957; Drs. K. R. Fawcett and Feuling, 1958, all of Duluth; and Drs. J. K. Butler, Cloquet, and J. A. Malmstrom, Virginia, 1959.

Alternate delegates: Drs. Josiah Fuller and F. W. Conley, 1957; Drs. J. D. Barker and H. J. Walder, 1958, all of Duluth; and Drs. H. H. Joffe and Paul Reed, both of Virginia, 1959.

* * *

Dr. Wallace E. Anderson, Clearbrook, has been elected 1957 president of the Red River Valley Medical Society. Other officers include: Dr. Byron Kinkade, Ada, vice president, and Dr. R. O. Sather, Crookston, secretary-treasurer. Dr. E. E. Pumala, Warren, was elected to the board of censors; Dr. George Sather, Fosston, was elected delegate to the Minnesota State Medical Association with Dr. O. K. Behr, Crookston, alternate delegate.

These physicians were elected at the December meeting of the group. Speaker for the meeting was Dr. John

McKelvey, chief of the Department of Obstetrics and Gynecology at the University of Minnesota, who discussed reasons for the decline in maternal mortality in the state since 1941.

* * *

Dr. and Mrs. A. R. Neff, Crookston, entertained the members of the Woman's Auxiliary to the Red River Valley Medical Society at the December meeting of the group.

* * *

Dr. and Mrs. G. E. Nelson and Dr. and Mrs. J. L. Haas, Fairfax, were hosts to the Renville-Redwood Medical Society and its Auxiliary at a Christmas meeting in December. Dr. A. W. Deissner, Redwood Falls, was elected new president of the Society; Mrs. Deissner the Auxiliary president.

* * *

The Scott-Carver Medical Society held its December meeting in Jordan at the Colonial Club. Attending from Shakopee were Dr. L. H. Heinz, Dr. I. B. Hein, Dr. and Mrs. B. F. Pearson and Dr. and Mrs. J. J. Ponterio.

* * *

Dr. O. B. Fesenmaier, New Ulm, has been appointed second district public health officer to fill the vacancy created by the death of Dr. H. J. Nilson, North Mankato.

* * *

Dr. Thomas E. Vanderpool, Litchfield, has been elected secretary-treasurer of the staff of Paynesville Community Hospital. New staff members include Drs. Frank J. Ankner, Minneapolis, John W. Docksey, Roger J. Michels, Austin M. McCarthy, all of Willmar, and Rosemary R. Frear, Broton.

* * *

Mrs. John F. Pewters, mother of Dr. John T. Pewters, Minneapolis, died December 24, in Seattle, Washington.

* * *

Dr. James Dokken, Windom, was the featured speaker at the November meeting of the ninth district nurse association. His topic was tranquilizing drugs. He also discussed the book "How to Live 365 Days A Year." The meeting was held in Mountain Lake.

* * *

Dr. Frederick S. Schnell, president of the Kandiyohi Swift-Meeker County Medical Society, presided at the annual Christmas meeting of the group held in Willmar. Dr. Roger P. Michels, Willmar, led the group in community singing, and the featured speaker of the evening was Wilbur Elston, editorial page editor of the *Minneapolis Star and Tribune*, who discussed the Middle East situation.

* * *

As of February 1, 1957, Dr. William A. Chervena

(Continued on Page A-44)

* * *

Dr. Joseph J. Garamella, clinical instructor in surgery at the University of Minnesota Medical School, has been named the first appointee to the Rappaport Professorship of Cardiac Research at Mount Sinai Hospital, Minneapolis. The professorship was established in 1955 with an initial gift of \$55,000 by the Rappaport family of Minneapolis, and provides for a permanent research post to be occupied by a medical scientist designated by the University of Minnesota. Dr. Garamella, age thirty-seven, is a thoracic surgeon, who has devoted the last two years to the investigation of surgical aspects of coronary heart disease and allied problems at Mount Sinai. He is a diplomate of the American Board of Surgery and the American Board of Thoracic Surgery. One of his research problems will be the use of surgical means of improving the circulation of coronary arteries.

* * *

At the January 8 meeting of The Minnesota Society of Neurology and Psychiatry, Dr. Richard M. Magruder presented his inaugural thesis on "An Operational Classification of Psychosomatic Disorders." By invitation, Drs. Ralph Suechting and Lyle French discussed "Isotope Encephalometry."

* * *

Drs. G. K. Stillwell, instructor in physical medicine and rehabilitation, and Khalil G. Wakim, professor of physiology, at the Mayo Foundation, Rochester, were among a group of national authorities in physical medicine who served as the faculty at a three-day symposium, December 6-8, 1956, at the University of Minnesota Center for Continuation Study, sponsored jointly by the University of Minnesota and the Sister Elizabeth Kenny Institute.

* * *

On December 1, 1956, Dr. Richard W. Anderson joined the staff of the new East Range Clinic at Aurora, Minn. The Range is not new to Dr. Anderson, since he was born at Hibbing, graduated from high school in Keweenaw, Minn., and attended Hibbing Junior College. He is a graduate of the University of Minnesota School of Medicine, and served with the U. S. Air Force.

* * *

Dr. and Mrs. Charles W. Mayo of Rochester attended a dinner and program honoring Prime Minister Nehru of India in New York, December 19, 1956. Dr. Mayo, a former U.N. alternate delegate, introduced Mrs. Eleanor Roosevelt, who in turn introduced Prime Minister Nehru to the audience.

* * *

Dr. and Mrs. John C. Wohlrabe, St. Clair, are the parents of a daughter born December 21, 1956.

* * *

At the December 12, 1956, meeting of the Minnesota Academy of Medicine, held at the Town and Country Club in St. Paul, there were forty-four members present. Dr. F. H. K. Schaaf, Minneapolis, read a paper entitled

His subject was "Comparative Diagnostic Approaches in Dermatology and Internal Medicine."

* * *

Dr. Edgar V. Allen, internist of the Mayo Clinic and professor of medicine in the Mayo Foundation, Graduate School, University of Minnesota, addressed the Indiana Heart Foundation in Indianapolis on January 31; the Louisville Heart Association in Louisville, Kentucky, on February 2; and the Minnesota Heart Association in Minneapolis on February 4, on the subject, "The American Heart Association."

Dr. Allen is president of the American Heart Association.

Book Reviews

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

THE MECHANISMS OF HEALING IN HUMAN WOUNDS. Shattuck W. Hartwell, M.D. Springfield, Illinois: Charles C Thomas, 1955.

Every physician, regardless of specialty or type of practice, depends in some degree upon the healing of wounds for the ultimate survival of his patient. The healing of wounds plays a vital role in the practice of medicine, and beyond that, in the survival of the species. It is the obligation of every physician, and more especially to those of us who create surgical wounds, to assist rather than retard the normal healing process. This monograph by Dr. Hartwell provides basic information to be used by all of us.

In a clear, concise manner the author presents his own observations on human wound healing and emphasizes the differences between data collected from animal experiments and those few observations that have been made in human surgical wounds. The author divides wound healing into two separate processes, epithelial and sub-epithelial healing, distinctly different but interdependent. Without boring the reader, a cell by cell description of these two healing activities is given and the practical applications of these microscopic observations are clearly outlined. During the brief time required for the reading of these 150 pages, the reader will begin to appreciate the skin as a functioning organ and not merely a haphazard envelope for the body. In the chapter, the author gives a layer by layer description of the healing process as it involves a typical abdominal incision, and provides a sound physiologic basis for the repair of surgical wounds with regard to fibrous healing and the functional stress applied to the wound.

It is not often that a book can be recommended to every physician, but occasionally information of a fundamental nature becomes available and should be acquired by every practitioner of the healing art. This monograph would appear to fit those qualifications and the reviewer urges every physician to avail himself of the facts and observations presented in such a readable manner by Dr. Hartwell.

Physician, Los Angeles County Hospital; Junior Attending Physician and Diplomate, Children's Hospital Cardiac Department, Los Angeles, California. Price \$5.00. 286 pages, illus., cloth. Philadelphia: Lea Febiger, 1955.

To review a book on electrocardiography one ought to know his physics and his physiology. The reviewer claims very little resemblance to a physicist; he does know some physiology.

As a clinician I started reading electrocardiography on the machine made by Hindle (now Cambridge). It resembled a modern electrocardiograph less than an old Ford resembles a modern automobile. With this machine and a few articles on electrocardiography I stumbled along. Sir Thomas Lewis' book "The Mechanism and Graphic Regulation of the Heart" came out about the same time. That helped a great deal. Then Pardee's book came out in 1924. After that I used Pardee's book as a guide and source of information. Then Ashman and Hull's book came out in 1937 followed by Burch and Winsor's Primer in 1945. The Primer has been my guide through the years. Comparing the 1945 edition with the most recent one in 1955 there is nothing new added to it. The format, however, is such better

To me, the application of Victor and Spatiel electrocardiography are still in the experimental phases. The ventricular gradient may be of some practical purpose. The time consuming features of the just enumerated studies of electrocardiography are such that when the question arises it can be referred to the laboratories of the initiators.

The third edition of "A Primer of Electrocardiography" by Burch and Winsor can be highly recommended to the student who is just beginning and also to the clinician who feels the need of refreshing his knowledge of the fundamentals.

Personally this book is not a primer; to me it is a text which I consult frequently.

AMERICAN CANCER SOCIETY BOOKLET AVAILABLE

The American Cancer Society is making distribution nationally to doctors of a booklet titled "The Physician and the American Cancer Society." Purpose of the presentation is to show the scope of the Society's overall program in relation to the professional aspects heretofore treated separately in other ACS publications. The work which supplements the well-known ACS Monograph series, is being sent to the entire membership of the American Medical Association, to interns, residents and senior medical students. Total distribution will run to about 250,000.

The booklet contains thirty-two pages, with two-color cover, and is generously illustrated. It treats with the Society's involvement in research and outlines service to patients, as well as its public and professional education programs. It gives a capsule history of the Society, its organizational philosophy, its guiding principles. Also provided is a listing of ACS publications and materials of special interest to doctors, and the addresses of the sixty ACS Divisions where they may be obtained.

Original Contributions

Sarcoidosis

Report of Eighteen Cases

JOSIAH FULLER, M.D.
FRANK J. HIRSCHBOECK, M.D.
Duluth, Minnesota

BOECK'S sarcoid, long felt to be primarily a skin disorder, has been known to involve any organ or tissue. Since lesions demonstrated on chest roentgenograms are being more accurately investigated, it is becoming apparent that the systemic form of the disease is actually more common. As the disease is of unknown etiology, since there is debate about the nature of the pathologic process and since there is disagreement about the prognosis of the condition, we believe that an effort should be made to report groups of cases that have been subjected to clinical and laboratory observation. The following is a report of eighteen patients who have been studied at the Duluth Clinic.

These patients have been followed from one month to six years with an average period of observation of twenty-two months. The average age of the group was forty-four years, with a range of twenty-six to sixty-five years. Seven of these patients were men.

Table I is a list of the clinical manifestations in these eighteen patients. Cough, enlarged peripheral lymph nodes and chest pains were the most common complaints. One of the five patients had lost seventy pounds. One of the five patients with arthritis had rheumatoid spondylitis and the rest had episodes of acutely painful swollen joints resembling in many respects the joint involvement of erythema nodosum.

Some of the more uncommon manifestations were interesting. The patient with fatigue presented himself to his physician for investigation of a chief complaint of fatigue. Peripheral neuritis involved the sixth, seventh, and eighth cranial nerves in a woman aged thirty-seven. Spontan-

eous pneumothorax occurred in a woman with very considerable pulmonary fibrosis. Three patients had erythema nodosum. Lofgren¹ has concluded that this indicates a primary stage of the sarcoidosis.

TABLE I. BOECK'S SARGOID

Clinical Manifestations—Eighteen Patients

Cough	8
Peripheral nodes	8
Chest pain	7
Weight loss	5
Arthritis	5
Dyspnea	5
Iritis	4
Abdominal pain	4
Erythema nodosum	3
Fever	2
Skin lesions	2
Fatigue	1
Parotid inflammation	1
Peripheral neuritis	1
Spontaneous pneumothorax	1
No symptoms	0

It should be noted that none of the patients was asymptomatic. Sarcoidosis is rarely an incidental finding in an individual who feels well, yet physical findings often outweigh symptomatic evidences.

The results of some of the laboratory tests were worth noting. A tuberculin skin test was done on sixteen patients and was negative in all except one who is negative to 0.1 mg. old tuberculin but positive to 1 mg. The erythrocytic sedimentation rate was elevated in thirteen of the fifteen patients for whom it was measured. The proteins were studied in eleven patients. The total serum proteins were above normal range in six patients averaging 8.6 grams per cent. The serum globulin was elevated in four, averaging 3.9 grams per cent and the albumin in two patients averaging 5.9 grams per cent. However, we did not consider this slight change in the proteins to be significant.

Presented at a meeting of the Minnesota Academy of Medicine, April 11, 1956.
From the Department of Thoracic Surgery and Internal Medicine, The Duluth Clinic.

Chest roentgenograms were made in all eighteen of these people with Boeck's sarcoid. In order to summarize the findings, the patients have been placed in groups according to the appearance of their roentgenograms. Figure 1 is an example of enlargement of the hilus and mediastinal lymph nodes without pulmonary parenchymal involvement. Seven of these eighteen patients had roentgenograms that resembled Figure 1.

Figure 2 is an illustration of an x-ray appearance that we have termed coarsely nodular and reticular. Note the small spontaneous pneumothorax. The nodules in the pulmonary parenchyma are gross and the reticulated appearance is in the form of a coarse network. These same findings were present in five patients, in contrast with the appearance of the film shown in Figure 3. This we have termed finely nodular and reticular. The nodules are so small they could be called military, yet close observation will disclose a reticulated pattern in the infiltrate. This was found at some time in three patients in this series.

For lack of a better term we have called the x-ray findings represented by Figure 4 "soft fluff." Four of these patients had radiographic findings that resembled this picture. In only one of the eighteen patients was the x-ray examination negative during the entire period of observation.

Serial chest roentgenograms on patients with pulmonary or mediastinal changes due to Boeck's sarcoid are characterized by their instability. In two of our patients the hilar lymph nodes regressed as the parenchymal changes appeared. This has been noted previously by Lofgren.² There was no change in the x-ray findings in six patients during the period of observation, and in four patients who showed changes the most recent chest films are now negative. There is definite improvement in the radiograms in three patients and in six of them the condition is worse.

X-ray examination of the hands was made in five patients and was negative in all.

All of these eighteen patients had histologic examination of tissue that was interpreted as being consistent with Boeck's sarcoid. In each case the tissue showed epithelioid cell granulomas without caseation. According to Siltzbach,³ the hard tubercle may also be found in tuberculosis, leprosy, histoplasmosis, berylliosis and brucellosis. However, when a typical clinical picture is com-

bined with the histologic appearance of noncaseating granuloma that exhibits a peculiar uniformity of stage of development in each tubercle, it is safe to make a diagnosis of Boeck's sarcoid. Furthermore, we send a portion of the excised tissue to the laboratory separately in a sterile container so that it may be cultured for bacterial pathogens, acid-fast bacilli and fungi.

In sixteen patients the scalene or cervical lymph nodes were the source for the biopsy material. In two cases a liver biopsy showed the characteristic histologic picture, and the bone marrow, skin, and hilus lymph nodes each showed a positive biopsy on one occasion. It will be noted in Table I that only eight patients had palpable peripheral lymph nodes yet we obtained positive lymph node biopsies in sixteen of the patients. Even in the absence of palpable lymph nodes, it is often possible in the presence of Boeck's sarcoid to obtain a positive biopsy by excising the fat pad with contained lymph nodes that lie on the anterior surface of the scalenus anticus muscle. This method, useful in diagnosing many obscure intrathoracic diseases, was described by Daniels⁴ and has been modified by others.⁵⁻⁹

We endeavor to keep the operation simple and do most of them under local procaine hydrochloride infiltration anesthesia in a manner similar to that described by Daniels. An incision is made parallel to and 1 cm. above the clavicle, extending laterally from the medial border of the clavicular head of the sternocleidomastoid muscle almost to the edge of the trapezius muscle. The dissection is carried below the omohyoid muscle. The fat pad and contained lymph nodes lying on the scalenus anticus muscle is removed *in toto*. The carotid sheath, subclavian artery and vein, pleural cap and brachial plexus border in the field of operation and the phrenic nerve, transverse scapular and deep transverse cervical artery and thoracic duct are frequently encountered in the dissection.

Anatomic investigations⁵ have shown that in most cases it is best to explore the right scalene area since the lymphatics from the right lung and the lower portion of the left lung drain to the right side.

Eight of our patients have received cortisone. Three of them received the drug more or less empirically elsewhere before the diagnosis was made. At the Duluth Clinic we reserve cortisone

for the patients with serious extra-pulmonary involvement or progressive symptomatic pulmonary disease. There can be no question that it has been of very material benefit in the five

symptoms which are not considered disabling and three of them are suffering from an appreciable disability. Although the number of patients in this series is much too small to draw any conclu-

patients to whom it was given for treatment of diagnosed Boeck's sarcoid, although there must be a careful check for possible untoward developments.

The prognosis of sarcoid as recorded in the literature varies all the way from the 19 to 25 per cent mortality described by Riley¹⁰ and Reisner¹¹ to the report of Carr and Gage¹² who concluded, after studying 194 patients, that the five-year survival rate of patients with sarcoidosis was 92.9 per cent, while that of a similar normal population was 99.5 per cent.

None of our eighteen patients has died. Seven of them are completely asymptomatic. Eight have

sions of statistical significance, it is interesting that all of the patients in the disabled group complained of cough and dyspnea and had a chest roentgenogram that appeared coarsely nodular and reticular, whereas only one of the patients who eventually became asymptomatic ever complained of dyspnea or had these x-ray findings, and only two of them had a cough.

We believe it is best to be optimistic when discussing the future with most patients with Boeck's sarcoid, unless they have severe and persistent disabling symptoms.

Pheochromocytoma

Report of Two Cases

J. ALLEN WILSON, M.D.
Saint Paul, Minnesota

PHEOCHROMOCYTOMAS are tumors formed from primitive cells derived from the neural crest. They may occur in the adrenal medulla or at other locations within the sympathetic nervous system. In a series of 139 cases, the tumors were located as follows:

Right adrenal.....	72
Left adrenal.....	44
Both adrenals.....	13
Intra-thoracic	4
Intra-cerebral	1
Right aortic ganglion.....	2
Left aortic ganglion.....	2
Zuckerkandl's ganglion (at bifurcation of aorta).....	2

These tumors may consist only of small focal enlargements in the adrenal medulla or become as heavy as 3,197 grams. The outer border of the smaller tumors is composed of adrenal cortex. The outer surface of the tumor varies in appearance from a pale gray or pink to a dusky brown. Cross section often shows evidence of necrosis and cystic formation. The microscopic appearance varies considerably. Most are benign but about 8 per cent of the tumors so far reported have been malignant. Marked pleomorphism may be found even in benign tumors; hence, a diagnosis of malignancy cannot be made on the basis of the microscopic picture but rather by the presence of local or capsular invasion or distant metastasis. The tumor tissue must give a positive chomaffin reaction before a diagnosis can be made. This reaction is produced by treating the tumor tissue with a chromatic solution, resulting in a brown stain in the cytoplasm of some of the cells.

Clinically, pheochromocytomas manifest themselves in one of four ways: (1) With paroxysmal hypertension (adrenal-sympathetic syndrome); (2) with persistent hypertension mimicking essential or malignant hypertension; (3) with a combination of hypertension, hypermetabolism and

glycosuria; and (4) with persistent hypermetabolism or hyperglycemia coexistent with intermittent hypertension. Goldenberg and associates³ stated that if tumors of the adrenal medulla functioned in the manner of the normal medulla, resting secretion would be negligible, and a discharge of epinephrine or norepinephrine would occur only upon physiologic stimulation (such as by acetylcholine or histamine). This is true in about a quarter to a third of the cases studied. The resulting clinical picture is that of paroxysms (adrenal-sympathetic syndrome) similar in manifestations to the effects of a rapid intravenous injection of a pharmacologic dose of epinephrine or norepinephrine or both. The chief features of such an attack are a steep rise in blood pressure associated with pallor, tachycardia, precordial and upper abdominal pain, hyperglycemia and anxiety, all or some of which may last for a few minutes to several hours. The attack usually then subsides but occasionally leads to fatal pulmonary edema or ventricular fibrillation.

Observations on cases in which paroxysmal hypertension occurs with persistent hypermetabolism or persistent hyperglycemia suggest that the "resting" secretion of these tumors may not be negligible although insufficient to produce elevated blood pressure. Apparently the metabolic effects are caused by much smaller doses of epinephrine than are needed to produce hypertension.

More often the tumors produce persistent hypertension associated with continuous secretion of epinephrine or norepinephrine or both. Small tumors, containing norepinephrine predominantly but not more than a total of 80 milligrams of this chemical, give rise to a syndrome resembling essential hypertension not accompanied by striking metabolic features. In patients with tumors containing larger total amounts of norepinephrine, hypermetabolism and hyperglycemia are more marked even though norepinephrine produces the

Inaugural thesis presented before the Minnesota Academy of Medicine, November 9, 1955.

atter to a much lesser degree than does an equal amount of epinephrine. When epinephrine is the predominant catecholamine in the tumor, hypertension, hypermetabolism, hyperglycemia and tachycardia are all prominent clinical manifestations.

In about 10 per cent of cases of tumors containing a large amount of epinephrine with a clinical picture of essential hypertension, with normal heart rate, and absence of metabolic disturbance, a negative or equivocal response to benzodioxane may be obtained. This suggests that persistent hypertension in patients with pheochromocytoma is not invariably due to the presence in the circulation of sufficient epinephrine or norepinephrine to cause hypertension by direct cardiovascular action (such as it does in acute infusion experiments). This nonhumoral hypertension in some cases of pheochromocytoma limits the value of adrenergic blocking agents in the diagnosis of the disease and makes desirable a direct diagnostic method not depending on a variable pharmacologic response. Hence Goldenberg and co-workers began to work on a method for measuring the increased urinary output of these catecholamines.

Pheochromocytomas may be diagnosed first at autopsy (fifteen such cases were reported from one institution),⁸ but it is unusual for these deaths to be unrelated to the tumor. Of these fifteen deaths, twelve were due directly or indirectly to the tumor. Five of these patients died after operations for some other condition, some of which were relatively minor surgical procedures. This emphasizes the fact that pheochromocytomas render a patient especially susceptible to surgical shock. A pressor response is produced by anesthesia, and if such a response occurs the procedure should be postponed, if possible, until the cause can be ascertained. The usual causes of death in those cases diagnosed at autopsy are related to cardiovascular degeneration, which results in acute left ventricular failure, cerebrovascular accidents and chronic congestive failure.

Early reports indicated that paroxysmal hypertension was more frequent than persistent hypertension. This has been found incorrect and now it is found that about 70 per cent of the cases present as chronic or persistent hypertension.¹⁴ Probably most of the patients with functioning pheochromocytomas will progress to persistent hypertension if they live long enough. Paroxysmal attacks of adrenal-sympathetic syndrome may be su-

perimposed on persistent hypertension. It must be remembered that paroxysmal hypertension may be also a manifestation of other diseases than pheochromocytoma, such as eclampsia, lead poisoning, essential hypertension, nephritis, traumatic or vascular brain damage, or tabes dorsalis. These paroxysmal attacks in cases of pheochromocytoma tend to increase in frequency and severity as time elapses. They may be produced by emotional stress, change in body position, exertion, exposure to cold or massage of the abdomen. At times, a provoking mechanism cannot be determined.

The presence of an elevated basal metabolic rate or of hyperglycemia associated with hypertension should make one aware of the possibility of the patient's having a pheochromocytoma. These tumors may also cause some swelling of the thyroid gland, exophthalmus and an increased protein-bound iodine, and the BMR may temporarily be lowered by antithyroid drugs.¹⁶ The hypermetabolism may be present during the normotensive period between paroxysms of hypertension, but is most often seen in patients with persistent hypertension. In one series of eleven persons with persistent hypertension, ten had a BMR over 10 per cent and the average was +49 per cent. In the same report, only three patients of a group of fourteen with paroxysmal hypertension showed hypermetabolism.¹⁰ Several other reports mention the importance of hypermetabolism in hypertension.^{1,3,11,16,17} Hyperglycemia is of less frequent occurrence in patients with pheochromocytoma, but its occurrence in conjunction with hypertension should arouse one's suspicion of the presence of this tumor.^{1,3,5,10,11,17} It is stated that at the time a diagnosis of pheochromocytoma is made, about 10 per cent of the patients are being treated for diabetes.¹⁶ Hyperglycemia may be either paroxysmal or persistent; whether or not it is persistent does not depend on whether or not the hypertension is persistent. Clinically, the diabetes is similar to diabetes mellitus in that acidosis may occur and there is a good response to insulin. The development of hyperglycemia in this disease is dependent on the glycolytic effect of epinephrine on the liver. However, acidosis in patients with pheochromocytoma is associated with a normal or slightly increased content of glycogen in the liver, in contrast to glycogen depletion in the liver in the acidosis of diabetes mellitus.^{5,17,22} The explanation of this occurrence in epinephrine diabetes lies in an increased breakdown of muscle

glycogen and the resulting lactic acid is transported to the liver where it is resynthesized to glycogen. The explanation for the occurrence of ketosis in epinephrine diabetes is not known but it is postulated to be the result of increased fat catabolism by the direct action of epinephrine.^{5,17}

The difference in the ratio of secretion of norepinephrine and epinephrine should not influence too greatly the clinical manifestations of the tumor, since sudden release of large amounts of epinephrine will cause increased peripheral resistance just as does norepinephrine, and sudden release of large amounts of norepinephrine will cause metabolic changes, just as does epinephrine. At the level at which these substances are used by the body, epinephrine causes decreased peripheral resistance and metabolic effects, while norepinephrine increases peripheral resistance and has little metabolic effect.

In the reported cases of pheochromocytoma, there is associated multiple neurofibromatosis in about 5 per cent.¹¹ In a more recent report, the over-all incidence of an associated neurocutaneous syndrome is approximately 10 per cent.⁶ This syndrome includes multiple neurofibromatosis, von Hippel-Lindau disease, tuberous sclerosis, and the Sturge-Weber syndrome. The association with neurofibromatosis is certainly more than chance and this may also be true in the case of von Hippel-Lindau disease. So far there are no reports of the occurrence of pheochromocytoma in patients with tuberous sclerosis or the Sturge-Weber syndrome. There is a tendency for pheochromocytoma to be familial, and the familial nature of the diseases making up the neurocutaneous syndrome is well known. Long-term follow-up of patients with pheochromocytoma, when available, will determine whether more of these persons will show manifestations of the neurocutaneous syndrome at a later date. Neurofibromatosis of the intercostal nerves may produce bilaterally symmetrical notching of the ribs similar to that seen in coarctation of the aorta. If such notching is seen in a patient with hypertension who does not have coarctation of the aorta, the possibility of neurofibromatosis and pheochromocytoma should be suspected.⁶ Unusual manifestations of this tumor also include gastrointestinal hemorrhage¹⁰ and one case of an abscess caused by *Salmonella typhimurium* in a functioning tumor.⁹

The diagnostic methods used to establish the presence or location of a pheochromocytoma have

been of three main types, namely roentgenologic studies, pharmacologic tests and chemical examination of the blood and urine. At times massage of the abdomen has resulted in a strong pressor response but failure to obtain this response does not exclude the diagnosis of this tumor. A palpable tumor is rarely found. In one series of twenty-five patients, only two had a palpable mass and both tumors proved to be malignant lesions.

X-ray methods of diagnosis include (1) a flat plate of the abdomen, which is rarely of much help since the tumors are of low density;¹¹ (2) renal pyelography, which may show displacement or distortion of the renal shadow; (3) aortograms; (4) planigraphy of the renal areas; (5) perirenal injection of air; and (6) presacral injection of oxygen. Perirenal injection of air has largely been abandoned as being too hazardous, and presacral injection of oxygen may well also be regarded as a dangerous procedure, as evidenced by a report of three fatalities and two near fatalities secondary to this procedure.⁷ The two near fatalities presented the typical "millwheel" murmur of intracardiac air. Kvale, Priestley and Roth¹⁰ stated that localization of the site of the tumor by the above methods is not necessary, since bilateral exploration of the adrenal areas is now carried out at operation. Intrathoracic pheochromocytomas have all been visible on ordinary chest x-rays.

Pharmacologic tests for this tumor are divided into: (1) use of drugs that provoke a pressor attack by the release of pressor substances from the tumor and (2) use of adrenolytic substances that antagonize or inactivate pressor substances, thereby lowering the blood pressure. Usually the first group of tests is used if the blood pressure is below 170 mm. systolic and 110 mm. diastolic, and the second group of tests is used if the blood pressure is above this level. For the correct interpretation of these tests, the patient must have had no sedative drugs for twenty-four hours. Administration of the shorter acting antihypertensive drugs must be stopped on the previous day. Use of thiocyanates must have been discontinued for four to six days. No specific statement could be found about the effect of rauwolfia products on the tests. This drug is said to have a persistent effect for several weeks after its administration has been discontinued.

The pressor provocative drugs are histamine,²⁰ mecholyl bromide²³ and tetraethyl ammonium

chloride.²⁴ Of these, histamine is the most reliable, and the others are now seldom used. After basal conditions are established, 0.025 to 0.05 mg. of histamine base in about 0.5 cc. normal saline solution is injected rapidly intravenously. A positive test is indicated by an initial fall of blood pressure (which also occurs in normal subjects) followed by a marked pressor response (often a rise of over 100 mm. of mercury). As the test was first used, a positive test was one in which the blood pressure rose higher than it did on a previously performed cold pressor test. The latter test has been eliminated since a cold pressor test itself may provoke a hypertensive effect in a patient with a pheochromocytoma. It is agreed that the histamine test is a fairly reliable one, but some false negative and false positive tests have been recorded.^{1-3,11} Proof that a pressor response to the histamine test is actually the result of a release of pressor amines into the blood stream has recently been afforded with the finding that blood levels of pressor amines increase when a pressor response is produced.¹⁵ The method by which histamine produces this effect has been suggested to be the result of blood vessel dilatation in the tumor or perhaps a direct stimulating effect similar to that on the chief cells of the stomach.²

The two adrenolytic substances used in diagnosis of pheochromocytoma are benzodioxane and Regitine. Dibenamine, also once used, has been abandoned because of its side effects and because it also produces hypotension in the absence of pheochromocytoma. During the depressor state produced by dibenamine, which may last twenty-four to forty-eight hours, the blood pressure may not respond to pressor substances.¹¹

Benzodioxane was first reported to be a valuable adrenolytic agent in 1947.¹⁹ In the dose subsequently determined, benzodioxane was found to be adrenolytic only and not sympatholytic. The technique of the test calls for the intravenous administration of 10 mg. of benzodioxane per square meter of body surface, or 0.25 mg. per kg. body weight. The injection should require two minutes. A positive result is indicated by a sharp drop in both the systolic and diastolic blood pressure within one to two minutes. Most (97 per cent) of the cases of essential hypertension will show a rise of blood pressure during the test.¹² This rise may be preceded by a slight fall in pressure. Side effects include tachycardia, apprehension, clammy

extremities and occasionally an alarming pressor response. The separation of a positive from a negative test is almost always clear-cut. When properly performed, the benzodioxane test showed four false negative tests in seventy-two proven cases of pheochromocytoma and one persistently false positive in ninety-one cases of essential hypertension.³ Higher percentages of false negative tests are obtained by prolonging the injection period over two minutes. For routine testing, Regitine is preferred, but positive Regitine tests should be confirmed with the benzodioxane test. If a negative Regitine test is obtained when clinical suspicion of the existence of a pheochromocytoma is strong, the benzodioxane test should also be done.

The Regitine test was first used in 1949.¹⁸ The test is carried out by rapidly injecting 5 mg. of the drug intravenously after the blood pressure had reached a basal level, and determining blood pressure at thirty-second intervals for three minutes and then at one-minute intervals for seven more minutes. A positive test is indicated by a drop in systolic pressure of over 35 mm. Hg. and a drop in diastolic pressure of greater than 25 mm. Hg. with the maximum drop occurring within the first two minutes after the injection.¹² Using these criteria there are many borderline responses and many false positive tests. In one series of tests on 107 hypertensives there were four false positive tests¹² and in another series of ninety-one hypertensives, eight false positives.³ False negative responses have been reported and probably occur with about the same incidence as with benzodioxane.³ In the presence of uremia the Regitine test is unreliable, often giving a false positive result.

Because of the false negative and false positive tests using histamine, benzodioxane and Regitine, several workers have sought to determine catecholamine levels in the plasma and urine, thus hoping to provide more reliable means of diagnosis of pheochromocytoma. The crudest attempt to demonstrate the increased production of pressor amines in patients with this tumor has been the injection of 1 cc. of the patient's untreated urine intravenously into the vein of an anesthetized dog (Weiman, Back, Russo, Shoemaker and Wolf).²⁵ In several cases, this resulted in a prompt pressor effect of up to 60 to 70 mm. Hg. systolic blood pressure. After surgery in one case, injection into a dog's vein of 10 cc. of an

alcohol extract of 49 grams of the tumor produced a marked blood pressure elevation similar to that produced by 0.25 cc. of 1:1000 norepinephrine. In one of the patients whom I am reporting, the injection of 1 cc. and 2 cc. of the patient's urine did not produce any demonstrable pressor effect in a dog.

In much more refined chemical analyses of catecholamine levels in the urine, Goldenberg and his co-workers³ recently have described their studies in sixteen cases of pheochromocytoma, ninety-one cases of essential hypertension, thirteen normotensive healthy subjects, ten cases of Addison's disease and fourteen cases of essential hypertension following lumbar sympathectomy. The methods they used consisted in part of adsorption of the urinary catecholamines on precipitated aluminum hydroxide followed by elution, desalting, and concentration in vacuo. These extracts were studied by bioassay, paper chromatography, photofluorometric evaluation and absolute quantitation of norepinephrine and epinephrine by chemical methods. They concluded that photofluorometric evaluation of extracts of urine seems to constitute the most reliable test for pheochromocytoma. They devised a short screening method but found that any positive result using this screening method must be confirmed by the longer procedure. No false negative or false positive results were obtained by the longer method. These authors found that in patients with pheochromocytoma the urinary excretion of norepinephrine and epinephrine has been found consistently to be far in excess of the amounts excreted by normotensive and essential hypertension subjects. The quantities of these amines secreted in the urine represent only a small fraction of the total amounts secreted by the tumor. The fact that the catecholamine mixture of human urine, if tested by bioassay methods consists predominantly of norepinephrine and less than 15 per cent of epinephrine, suggests that its primary source is the sympathetic nervous system rather than the adrenal medulla. This assumption is easily proved, they say, for in Addison's disease the urinary excretion measured by bioassay as norepinephrine equivalent may be within normal limits. The lowest excretion rates were found in fifteen cases of essential hypertension following thoracolumbar sympathectomy. The authors found the urinary measurement of norepinephrine and epinephrine valuable for both

persistent and paroxysmal hypertension due to pheochromocytoma. A most surprising finding was the amount of "leakage" of catecholamines encountered in paroxysmal cases during the normotensive periods between attacks. To account for the lack of a pressor response to the relatively large amounts of norepinephrine secreted by some of the tumors between attacks, the authors felt tempted to speculate that an adrenergic blocking agent may have been secreted.

Another attempt at more accurate diagnosis of pheochromocytoma has been the venous plasma determinations of norepinephrine and epinephrine by Manger and his associates¹⁵ in thirteen patients with pheochromocytoma. Their method involved paper chromatography followed by elution and fluorometric quantitation of the pressor amines. In all their patients with sustained hypertension the preoperative levels of epinephrine and norepinephrine were significantly elevated. Two of their four patients with paroxysmal hypertension due to this tumor had elevated plasma levels of these pressor amines. The concentration of epinephrine and norepinephrine in the other two patients could be significantly increased by use of a provocative drug like histamine. The use of an anesthetic or palpation of the tumor in the abdomen was often associated with the release of considerable amounts of these catecholamines. They also found norepinephrine to be the major substance of these amines secreted in increased amounts.

In considering the use of determinations of pressor amines in the urine and plasma, it would appear that quantitation of urinary epinephrine and norepinephrine is apt to be more valuable. It has an advantage of measuring the result of secretion over long periods of time while measurements of the pressor amines in the blood reveal only what is present at the moment.

The treatment of pheochromocytoma is always surgical, once the diagnosis has been made. The abdominal approach is now used to facilitate exploration of both sides. At the time of anesthesia and during the entire surgical procedure (especially during manipulation of the tumor), a solution of Regitine should be at hand and 5 mg. of the drug should be administered intravenously at any time that the blood pressure tends to rise to dangerous levels. After removal of the tumor a constant infusion of 4 mg. of Levo-phed per liter of isotonic saline should be started and adjusted to

keep the blood pressure at normal levels.^{10,11} This is more apt to be necessary in patients who have had persistent hypertension rather than in the paroxysmal type prior to surgery. A precipitous fall of blood pressure usually occurs in the persistent hypertensives with the removal of the tumor. If this does not occur, one should suspect the presence of a second tumor. The Levophed support of blood pressure may be needed for from one to three days after surgery. If bilateral tumors are found, the surgeon can usually leave some adrenal cortex but intravenous hydrocortone should be available at surgery to treat possible adrenal cortical insufficiency. In a group of twenty-five cases recently reported,¹⁰ there was no operative mortality. Before the patient is discharged a histamine provocative test should be done.

Surgical cures have been the rule, except in patients having malignant tumors. In a group of twenty-three cases followed two to seven years postoperatively it was found in every case that the patient was cured of his symptoms.¹⁰ Even the patients who had group 3 or 4 hypertension before surgery were found to have normal or near-normal blood pressures and the ocular fundi changes had reverted to normal or near-normal.

The two cases of pheochromocytoma reported below were diagnosed at the Minneapolis Veterans Hospital. One patient with paroxysmal hypertension was diagnosed by the author, and the patient with persistent hypertension was seen on another medical ward and the diagnosis established by a very able resident, Dr. Vernon Vix. Both patients were treated surgically with success.

Case Reports

Case 1 (Paroxysmal Hypertension).—J. G. A., a twenty-seven-year-old man, was admitted to the hospital on April 1, 1948. His complaints were attacks of palpitation, nervousness and fatigue for five years beginning while on military service in the South Pacific. The attacks of palpitation, flushing and extreme nervousness would last from a minute to ten minutes. They seemed to be precipitated by fatigue. He was seen by many Army physicians who noted only mild hypertension except on one occasion when the blood pressure was recorded as 225/140 during an attack. Gradually the attacks became more frequent and were accompanied by pain in the precordium, posterior cervical and left orbital areas. He felt well between attacks. A typical seizure was described as starting with palpitation, then flushing, then perspiration, then nausea and pain followed by nervousness and fatigue.

He had been admitted to this hospital in August, 1947, for operation of a fistula in ano. His blood pressure then had been recorded as 146/80. In March, 1948, he had been referred to the hospital by the out-patient clinic where his basal metabolic rate had been done at the request of a private physician. It was +85 per cent. He was admitted to the hospital with a tentative diagnosis of probable hyperthyroidism and anxiety state.

Physical Examination showed the patient to be extremely anxious and concerned about his condition. He feared he had a mental disorder. He had a marked increase in heart rate and forcefulness of beats when changing from a supine to a sitting position. His blood pressure was 150/100. The ocular fundi were normal and he had no exophthalmos.

Laboratory Findings: Routine blood and urine determinations were normal. Three BMR readings were normal. A glucose tolerance test was normal, as was a chest roentgenogram. An I-V urogram was reported as normal, but on retrospect a possible mass was noted over the upper pole of the left kidney. Perirenal air insufflation showed a distinct globular mass over the upper pole of the left kidney. An intravenous histamine tolerance test was done by injection of 0.05 mg. of histamine base. The blood pressure did not show an initial drop, but rose within three minutes from 150/90 to 235/100, falling back to the base level in ten minutes. A cold pressor test a few days later produced only a slight rise in blood pressure. A day or two later, the patient was observed during a spontaneous pressor attack. His blood pressure was found to be 220/110, and it gradually dropped to the base level within ten minutes. Intravenous injection of 100 mg. of Etamon failed to produce the drop in blood pressure usually seen when injected into the ordinary hypertensive patient.

A diagnosis of pheochromocytoma of the left adrenal area seemed most probable. The patient was submitted to surgical exploration. During manipulation of the tumor the blood pressure rose sharply to over 200 mm. Hg. systolic on three occasions. After removal of the tumor, the blood pressure dropped to 90/50. Much of the normal adrenal gland was left *in situ*. The blood pressure after removal of the tumor was controlled by a slow intravenous infusion of adrenalin solution. The tumor weighed 66 grams and measured 5 cm. in diameter. Microscopic examination confirmed it as a pheochromocytoma with no malignant cells seen. The cells were mostly of large polygonal shape with large hyperchromatic vesicular nuclei. The cytoplasm was abundant and acidophilic. A few spindle-shaped cells and some degenerative areas were seen. Postoperative convalescence was uneventful except for a temporary phlebitis in the right forearm and left leg. This was treated by rest, dicumarol, penicillin, and later by physiotherapy. His postoperative blood pressure averaged about 128/80. One week after surgery, the I-V histamine test was repeated. There was an immediate drop in blood pressure followed by a slight rise to 150/90.

The patient was discharged in excellent condition.

Case 2 (Persistent Hypertension).—H. H., a thirty-one-year-old white man, was admitted to the Minneapolis Veterans Administration Hospital on November 9, 1954. He had entered military service in World War II. In 1945, at the age of twenty-two, he had been rejected for officer-candidate training because of hypertension. After observation in an Army hospital he was returned to active duty. On discharge, from the service, he was given a 10 per cent disability rating for hypertension. He felt well and worked as an electrician until October, 1953. At that time he suffered a cerebrovascular accident involving the right side of his face, right arm and right leg, and loss of speech. These symptoms improved slowly during four months' hospitalization at the Fargo Veterans Administration Hospital. Since then he had been taking Rauvera tablets given by his own physician. He had frequent episodes of palpitation and throbbing frontal headaches especially when he was fatigued. These became severe about one month before admission. He had also noted some left flank discomfort. The patient's mother and sister were known to have hypertension.

Physical Examination revealed a pulse of 99 and blood pressure of 200 systolic and 130-110 diastolic. The ocular fundi presented Grade I hypertensive changes. The thyroid was not palpable. The precordium pulsed prominently. A grade III systolic murmur was heard in the left fourth interspace near the sternum. The blood pressure in the left leg was 220/140. No abdominal masses were palpated. Some residual weakness was noted in both right extremities and Hoffman and Babinski signs were noted. Mild facial muscle weakness was still present on the right.

Laboratory Findings: The hemoglobin measured 15.1 grams. Urinalysis showed a few white and red blood cells and a trace of albumen. The B.U.N. was 10 mg. per cent. A serologic test for syphilis was negative. The fasting blood sugar was 92 mg. per cent but a diabetic glucose tolerance curve was found. A P.S.P. test showed that 23 per cent of the dye appeared in the urine in fifteen minutes and 44 per cent in thirty minutes. Fluoroscopy and a P.A. roentgenogram of the thorax revealed no abnormalities. An I-V urogram was normal, except for a small calcific density in the right upper quadrant of the abdomen of unknown significance. Planigrams of both renal areas were normal. The BMR and EKG were normal. Radioactive iodine uptake by the thyroid gland was 24 per cent in twenty-four hours.

Hospital Course. One day after admission the resident physician, Dr. Vernon Vix, carried out a Regitine test. Five milligrams of this drug produced a drop in blood pressure from 210/126 to 144/90 in 100 seconds. Within ten minutes the blood pressure gradually rose to 186/116. Since the patient had been on antihypertensive drugs prior to admission, three more Regitine tests were carried out over the next three and one-half weeks while the patient was receiving no medication. These showed drops in blood pressure as follows: 200/108 to 124/74, 200/114 to 120/70, and 200/130 to 126/76. A Benodaine test was also done which produced a drop in blood pressure from 184/116 to 132/80. On November

22, one and two cc. of the patient's urine were injected intravenously into an anesthetized dog without any effect on the dog's blood pressure. At the time of the test the patient's blood pressure was only 146/100. The blood pressure was taken twice daily and fluctuated between 150/80 and 220/116.

The diagnosis was considered to be pheochromocytoma, so on December 22 an exploratory laparotomy was carried out. Cortisone was given preoperatively and for seven days postoperative. Both adrenals were explored. The left gland was normal. The right adrenal contained a tumor of 2 cm. diameter. The tumor with surrounding normal adrenal tissue was excised. During surgery the patient's systolic blood pressure fluctuated between 100 and 300 mm. Hg. Regitine solution was injected intravenously when the pressure rose steeply. Levo-phed or Aramine solution was injected during periods of hypotension to maintain a systolic pressure of around 170 mm. Hg. One pint of whole blood was given during the operation, blood loss being estimated at 250 cc. On the first postoperative day, the patient developed oliguria which lasted for ten days. The B.U.N. rose to a peak of 232 mg. per cent on the eleventh postoperative day. His potassium rose to a high of 5.15 Meq/L at that time. The serum amylase reached a high of 880 units per 100 cc. nine days after removal of the tumor. He was given the usual treatment for renal shutdown, including a Borst diet for a few days. The blood pressure stabilized at 150/100. At the time of discharge from the hospital the B.U.N. had returned to 20 mg. per cent and the patient felt well. Intravenous histamine was given during the postoperative period with no rise of blood pressure.

Pathologist's Report. The specimen weighed 11.8 gms. On section a thin rim of adrenal cortex was seen surrounding a tumor mass which occupied the entire medulla. It was of tan-gray color and rubbery consistency. A small amount of calcium was located in the middle of the tumor (corresponding to the calcific shadow seen on the intravenous urogram). At no point did the tumor penetrate the capsule formed by the adrenal cortex.

Microscopic examination of the tumor showed large cells having vesicular nuclei and of varied shapes (polyhedral, spindle or square). The cytoplasm was vacuolated and pink. Sections of the tumor fixed in bi-chromate solution showed many brown granules located in the cytoplasm of many of the cells. This was presumably an epinephrine-like substance. No evidence of malignancy of the tumor cells was noted.

Acknowledgment

I wish to acknowledge the assistance of Dr. Vernon Vix of Minneapolis in supplying the information for the second case report and for the help obtained from his résumé of this subject printed in the Minneapolis Veterans Hospital Grand Rounds, Volume XIV, No. 3, pages 21-31, 1955.

SARCOIDOSIS

(Continued from Page 143)

Summary and Conclusions

1. Eighteen patient with Boeck's sarcoid are presented who had histologic confirmation of the diagnosis and who were subjected to careful clinical and roentgenologic evaluation.

2. In our experience, sarcoid is a disease that frequently is overlooked because, though the patients have symptoms, they are not severe nor of a specific character. We feel that many cases are discovered when an awareness of its possible presence is in the mind of the physician. The illustrative cases seen by us, we feel, were quite definitive of sarcoidosis and no difficulty seemed to be encountered in classifying the disease state as such.

The Value of Biopsy of Lower Deep Jugular (Scalene) Nodes as a Diagnostic Procedure

OLIVER H. BEAHR, M.D.
OLIVER R. HUNT, JR., M.D.
OLIVER M. STORSTEEN, M.D.
PHILIP E. BERNATZ, M.D.

Rochester, Minnesota

MICROSCOPIC study of tissue is still the only absolute method of establishing a pathologic diagnosis in the presence of a tumor or other abnormal finding on clinical or roentgenologic examination. The historical aspects of removal of tissue for biopsy have been reviewed by Heinrich and Judd.¹ After positive diagnosis is made, the physician can better advise the patient regarding his condition and the therapy to be considered. For lesions which can be felt or seen, tissue for biopsy can usually be easily obtained as part of the planned surgical treatment of the disease. For instance, when a tumor of the breast is present, a specimen is easily removed for biopsy. If the tissue removed is malignant, a radical mastectomy can be carried out. If the results of the biopsy are negative with respect to a malignant lesion, a major surgical procedure is prevented. However, for certain intrathoracic or intra-abdominal lesions it is necessary to undertake a major surgical procedure if an absolute pathologic diagnosis is to be made. Considerable risk, discomfort and expense to the patient could be avoided if tissue could be obtained by a minor operation. In selected cases this problem has been solved by the removal of a lower deep jugular (scalene) node on the right or left side for study. The value of this procedure has been emphasized by Daniels² and others.³ The significance and value of removal of the sentinel node (Virchow's node) in the left lower cervical region is familiar to all physicians. Also, the significance of any abnormal lymphadenopathy should be recognized, especially in the presence of a known or suspected malignant lesion elsewhere in the body.

Read at the meeting of the Southern Minnesota Medical Association, New Ulm, Minnesota, September 10, 1956.

Dr. Hunt and Dr. Storsteen are Fellows in Surgery, and Dr. Behr and Dr. Bernatz are in the Section of Surgery, Mayo Clinic and Mayo Foundation.

The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

The lower deep jugular nodes on the left are closely associated with the thoracic duct. Because of this, many intra-abdominal and left upper pulmonary and mediastinal lesions spread to these nodes. The lymph drainage from the remaining portion of the thorax is into the right lymphatic duct and to adjacent right lower deep jugular nodes. The lymphatic drainage from the thorax has been discussed by Connar.⁴ As he has illustrated, the lymphatic drainage of the right lung and the left lower lung field is to the right lymphatic duct, while that of the left upper lung field is to the thoracic duct. The left middle lung field is either to the thoracic duct or to the right lymphatic duct via the lymph nodes of the tracheal bifurcation. Lesions in the neck or the oral cavity usually spread to nodes in the ipsilateral side of the neck and occasionally first to the lower deep jugular nodes. Because of the more or less orderly spread of selected lesions, as mentioned previously, if a lower deep jugular node could be removed for biopsy, an absolute diagnosis might be established by a relatively simple surgical procedure and in some cases the necessity of a major operation might be eliminated.

Although the removal of a lower cervical node is a minor surgical procedure, it is a technical one because of the anatomic relations involved and should not be undertaken with a feeling of impunity. We prefer to do a precise anatomic dissection in exposing the nodes. A linear incision is made about 1 to 2 cm. above the clavicle and over the depression between the two heads of attachment of the sternocleidomastoid muscle (Fig. 1). A longitudinal split is made between these two portions of the muscle, and the internal jugular vein is exposed. The vein is freed along its lateral border and then retracted medially. The vagus nerve and the common carotid artery should be medial to the vein but occasionally will be deep to it. Care should be taken to determine the loca-

TABLE I. PATHOLOGIC DIAGNOSIS IN THIRTY-FOUR CASES IN WHICH NONPALPABLE LOWER CERVICAL NODES WERE REMOVED FOR BIOPSY*

TABLE II. FINAL DIAGNOSIS IN FORTY-FIVE CASES IN WHICH BIOPSY OF NONPALPABLE CERVICAL NODES WAS NONCONTRIBUTORY

Diagnosis	Right	Left	Total
Indeterminate diagnosis	2	0	2
Indeterminate intrathoracic disease	12	3	15
Indeterminate pulmonary fibrosis	7	1	8
Boeck's sarcoid	3	0	3
Carcinoma of lung	8	2	10
Miscellaneous	5	2	7
Total	37	8	45

tion of these structures. In the deep area of the dissection the phrenic nerve should be seen on the scalenus anticus muscle. In the general area of the dissection, deep and lateral to the vein, the scalene fat pad containing multiple lymph nodes can be excised *en bloc*. When the dissection is carried out on the left, the thoracic duct should be kept in mind and protected.

In order to evaluate the removal of lower deep jugular nodes for biopsy as a diagnostic step, we have reviewed the case histories of 500 recent consecutive patients undergoing 503 surgical procedures. In seventy-nine instances there was no palpable lymphadenopathy and the procedure was carried out strictly as a diagnostic test, while in 424 instances clinically palpable nodes were present and removed for study. In the group of cases in which a node is not palpable, the procedure is considered to be a "blind biopsy."

Local anesthesia was used in 40 per cent of the cases, and no patient in this group required hospitalization. The remaining 60 per cent were given pentothal sodium, and these patients remained in the hospital one to three days. Many of these patients were already hospitalized because of their illness. Thirty-five per cent of the patients were female and 65 per cent were male. The ages ranged from eleven months to seventy-eight years.

There were no hospital deaths, and in only seven cases was there any significant morbidity; this was mainly bleeding, which was not serious in any case.

Fig. 1. The incision is situated over the depression between the two heads of the sternocleidomastoid muscle, and the dissection is carried deep and lateral to the internal jugular vein.

In 478 instances the biopsy was advised for diagnostic purposes, in twelve to aid in determining operability and in thirteen for diagnosis and to establish the operability of the primary lesion.

In thirty-four of the seventy-nine "blind biopsies" a positive pathologic diagnosis was established on study of the tissue, a diagnostic rate of 43 per cent (Table I). Study of the tissue in forty-five specimens was noncontributory in establishing a diagnosis. The final diagnoses in these cases are shown in Table II. Possibly had the blind biopsy been carried out on the right instead of on the left in eight of these instances, positive tissue could have been obtained, since the majority of thoracic lesions spread to the right. However, in the sixteen cases in which blind biopsy was carried out on the left, the intrathoracic lesions either were diffuse or were lateralized to the left.

Absolute diagnoses were established from 364 specimens of 424 removed from patients with palpable lower deep jugular nodes; this resulted in a diagnostic rate of 86 per cent (Table III). In sixty instances study of the nodes removed revealed no significant information toward establishment of a diagnosis. The final diagnoses in these cases, established by other measures, are shown in Table IV. In the group of 364 cases it is to be

*A positive diagnosis was established in 364 cases in a series of 424 in which biopsies were performed.

noted that the majority of specimens were taken from the left side. This is the result of a large number of cases of primary lesions of intra-abdominal and undetermined origin in which the surgeon felt that the spread along the thoracic duct to the left lower cervical nodes might make a biopsy on the left side more likely to be diagnostic.

Comment

Boeck's sarcoid was the established diagnosis in twenty of thirty-four positive blind biopsies and in thirty-three of the palpable node biopsies. Certainly, if sarcoidosis is suspected clinically, whether or not there is palpable lymphadenopathy, biopsy of the lower jugular nodes would, in many cases, establish the diagnosis. As a rule, if no nodes can be felt and if the suspected lesion is not situated in the left side of the neck or in the left upper quadrant of the thorax, the right side should be the site of the operation. Blind biopsy has not been carried out frequently for suspected intra-abdominal lesions, but, if it is being done for this, then the left side should be explored.

When nodes were palpable, the primary lesion was situated in the neck in 16 per cent of the cases. This percentage may seem somewhat low, since cervical nodes are being removed, but few primary malignant lesions in the head and neck spread initially to the lower deep jugular nodes before declaring themselves clinically or developing metastatic lesions which can be detected clinically in the upper or middle or other groups of cervical lymph nodes. In fact, the nodes which we are discussing should probably not be considered primarily cervical nodes, since they are

terminal nodes for the lymph drainage of many areas of the body. The twenty-two specimens removed for biopsy and reported as inflammatory represent specific infections, such as tuberculosis, and not nonspecific inflammatory reactions, and because of this are considered positive biopsies.

Approximately 20 per cent of the palpable nodes removed established a diagnosis of carcinoma of the lung. In practically all of these patients a major thoracic operation was prevented, since spread to these nodes, as in the group of cases in which abdominal lesions were present, indicated that the carcinoma was beyond the confines of surgical removal, a point which has been made by Connor. The various cell types of carcinoma of the lung found in the seventy-two cases are shown in Table V. While squamous cell carcinoma represents about 40 per cent of all carcinomas of the lung, less than 20 per cent of the metastatically involved lymph nodes were of this type. Squamous cell carcinomas of the lung have been shown to spread to mediastinal lymph nodes less frequently than other types. Small cell carcinoma, representing only 10 per cent of all resected carcinomas of the lung, was found in 31 per cent of the node biopsies, and such a finding is in keeping with early metastasis to lymph nodes and a known poor prognosis.

Metastatic carcinoma of the breast was diagnosed in thirty cases. In all of these cases mastectomy had been performed previously and positive cervical nodes were evidence of metastatic spread of the original disease.

In 13 per cent of biopsies the primary lesion was found to be in the abdomen; forty-three were carcinomatous in type and three were lymphomatous. The various sites of primary carcinomatous lesions are shown in Table VI. Almost one half of the lesions were situated in the stomach. In the six instances in which the biopsy was carried out on the right side, either diffuse carcinomatosis was

TABLE V. CELL TYPE OF CARCINOMA OF THE LUNG IN PALPABLE CERVICAL NODES REMOVED FOR BIOPSY

Cell Type	Right	Left	Total

present or the lesion was situated in the upper portion of the stomach, involving the esophago-gastric junction.

In a large group of specimens, representing 18 per cent of the positive biopsies of palpable nodes, the type of carcinoma could not be identified or the primary site located. For the most part these lesions were highly undifferentiated carcinomas.

The bacteriologist plays a prominent role in increasing the value of the procedure of biopsy of lower deep jugular nodes. A portion of each specimen is placed by the surgeon in a sterile container. If the pathologist can make a positive diagnosis of neoplasm with the frozen sections, bacteriologic studies are not necessary. Likewise, if there is no evidence of specific inflammation, for instance, granulomatous or pyogenic reaction, culture studies have been shown to be of no value. If the frozen sections reveal a granulomatous reaction or other evidence of specific inflammation, the portion of the specimen in the sterile container is sent for bacteriologic studies. These may prove extremely valuable in the solution of certain difficult diagnostic problems. Heinrich and Judd¹ and Weed and Dahlin⁵ have similarly stressed this point.

It is apparent from the results of this study that biopsy of lower deep jugular nodes is a valuable diagnostic aid. The procedure certainly should be considered whenever a node in the lower cervical region is palpable and is thought to be abnormal. In selected cases of suspected intrathoracic lesions and in a few instances of intra-abdominal lesions, biopsy of a lower jugular (scalene) node should be considered even though no node is palpable clinically.

The indications for removal of a lower deep

jugular node for biopsy are as follows: (1) Lymphadenopathy or palpable nodes; (2) clinical or roentgenologic evidence or both suggesting (a) Boeck's sarcoid, (b) lymphoma, (c) malignant intrathoracic or abdominal lesions or (d) pulmonary inflammatory disease of granulomatous nature; and (3) to determine operability of intrathoracic or intra-abdominal malignant lesions.

Summary

Removal of lower deep jugular (cervical-scalene) nodes for biopsy in the presence of suspected intrathoracic or intra-abdominal lesions is considered a valuable diagnostic aid. Five hundred and three biopsies in 500 consecutive patients were evaluated. In seventy-nine instances in which the procedure was carried out in the absence of palpable nodes, the positive diagnostic rate was 43 per cent. In 424 biopsies in which abnormal nodes were palpable the diagnostic rate was 86 per cent. The operation is a technical but safe procedure and can be carried out with minimal morbidity and mortality.

Relationship of Endometrial Hyperplasia to the Etiology of Adenocarcinoma of the Endometrium

ERNEST W. LOWE, M.D.

Minneapolis, Minnesota

SCHRÖEDER'S¹ concept of persistent estrogenic stimulation unopposed by progesterone is generally accepted as the explanation of the etiology and of the histologic pattern of endometrial hyperplasia. This implies that hyperplasia is associated with the anovulatory type of cycle. The follicle or follicles not only fail to rupture, but continue to function beyond the usual ovulation period so that a persistent growth effect is produced upon the endometrium. Persistent estrogen from any other source will produce the disease. Exogenous estrogen will produce it in the castrate or after the menopause.

The factor which checks continued function of the follicles is believed to be an inhibition of the anterior pituitary gonadotropin formation with consequent withdrawal of the stimulus to follicle function and withdrawal of estrogen.² A bleeding phase results and this seems to be associated with lowered levels of estrogen excretion.

Following the menopause, this hormonal stimulation may arise from functioning ovarian tumors, namely, granulosa and theca-cell tumors. Hyperplasia, in the postmenopausal woman, may develop without an obvious source of estrogens. The estrogens in these cases may arise from the adrenals or from hypertrophic stromal cells near the ovarian hilum.^{3,4}

Authors engaged in serious studies of endometrial hyperplasia are not far apart in their views on the etiology or physiopathologic process of the disease. However, the clinical significance of hyperplasia, its relation to endometrial carcinoma and the proper safe treatment of the disease have been the source of much disagreement.

A study was undertaken at the University of Minnesota Hospitals to review our experiences with endometrial hyperplasia. One hundred and sixty-two cases of endometrial hyperplasia were treated at the hospitals during the ten-year period

from 1939 to 1949. The diagnosis was suspected in most cases by the bleeding history, but in every case was confirmed by microscopic examination of the endometrium after curettage. The late Dr. Robert Meyer and Dr. John L. McKelvey reviewed all of the pathologic specimens.

Twenty-six patients, or 16.1 per cent of those studied, had one or more repeat curettages for the same condition. All others who returned to the clinic with a recurrent abnormal bleeding story within a three-month period were given definite therapy for endometrial hyperplasia according to age and associated pelvic diseases without further diagnostic procedures.

The age distribution (Table I) is almost identical with that reported by Schröder in 3,270 cases studied over a forty-year period.⁵ The last years of the reproductive period (ages thirty-six to fifty-five) gave rise to 74.1 per cent (120) of all cases. The first years of reproductivity (ages ten to twenty) produced eleven (6.8 per cent) cases. There were ten (6.3 per cent) instances of hyperplasia between ages fifty-five and seventy-five.

In the Minnesota material there was associated pathology in sixty cases. Two women, ages fifty-one and fifty-six respectively, had granulosa-cell tumors. Thirty-seven (23 per cent) had myomata uteri and twenty-one (13 per cent) had endometrial polyps.

In the treatment of endometrial hyperplasia rather clear-cut principles were followed. No patient received treatment until the diagnosis was established microscopically.

In general, treatment in this series was conservative and surgical interference as a primary attack was avoided. In those below the age of forty, curettage, improvement of general constitutional status, rapid treatment of anemia and cyclic progesterone as advocated by McLennan⁶ and Holmstrom⁷, were used. After age forty, similar principles were applied although x-ray sterilization was more liberally used, particularly

Department of Obstetrics and Gynecology, University of Minnesota Medical School.

in the presence of recurrence in the menopausal age group. The use of surgery was largely limited to those who had some associated pelvic disease.

During the ten-year period of this study, seventeen (10.5 per cent) were treated by hysterectomy. In each case, granulosa-cell tumors, prolapse or multiple or large myomata prompted the surgery.

X-ray sterilization was used in fifty (31 per cent) cases. Usually 600 to 700 tissue roentgens delivered diffusely to the pelvis at depth is an adequate dose to terminate ovarian function in a menopausal woman. X-ray sterilization is preferred to intrauterine radium because of the danger of infection, perforation and incomplete ovarian effect with the latter.

This conservative, nonsurgical approach to the handling of endometrial hyperplasia is obviously based on the conclusion that this condition is not a precancerous lesion and that x-ray irradiation in this dose does not give rise to malignancy. The present study is designed to test the reality of this.

Novak and Richardson⁸ consider atypical postmenopausal endometrial hyperplasia a premalignant condition. Novak and Yui⁹ feel that endometrial carcinoma and hyperplasia frequently coexist and reported the presence of endometrial hyperplasia in twenty-five of 104 cases of endometrial carcinoma. Arfwedson and Winbard¹⁰ report two cases of adenocarcinoma of the endometrium developing two years after radiotherapy for hyperplasia. Fremont-Smith et al¹¹ reported a patient who received estrogen therapy for eight years who developed, first, endometrial hyperplasia and then endometrial carcinoma. Hertig and Sommers¹² reported that cystic hyperplasia is a remote forerunner of endometrial carcinoma on the basis of reviewing the histologic material of thirty-two cases of endometrial cancer who had curettages from one to twenty-three years before frank invasive endometrial carcinoma was diagnosed.

Equally strong arguments can be found that

indicate that endometrial hyperplasia, though an extremely common disease, is unrelated to the subsequent development of endometrial carcinoma.

Fahlund and Broders¹³ doubt any such association of cancer with hyperplasia and suggest that endometrial carcinoma is more likely to occur in cases in which an atrophic endometrium is found.

Taylor¹⁴ feels that the relative frequency of hyperplasia undoubtedly indicates that the individual patient with the disease is relatively safe.

Schröder⁵ definitely concluded that hyperplasia is not a precancerous lesion on the basis of observing the development of only ten cases of cancer of the endometrium among 3,295 definite cases of hyperplasia studied over a forty-year period. This is an incidence of 0.31 per cent and is less than might be expected if the association occurred by simple unrelated chance.

An effort to check on our cases of endometrial hyperplasia treated at the University of Minnesota Hospitals between 1939 and 1949 was made by sending questionnaires to the patients. A period of seven to seventeen years had elapsed since the patients' initial therapy.

Information was secured on 139 of the 162 cases for a follow-up of 85.8 per cent.

Seven of the patients had died since leaving the hospital. One had cancer of the breast, and one a coronary thrombosis. Two had cerebral vascular accidents. One died of uremia and two from unknown causes. None had died of or with known pelvic carcinoma.

Seventeen of the patients subsequently had hysterectomies elsewhere and pathologic reports on the surgical specimens failed to produce a single cancer.

The remaining 115 patients who replied to our questionnaires were well and free of known cancer of the endometrium.

This study, of course, is inconclusive. The number of cases is small. Some may consider seven to seventeen years too short a period for the patients to develop their cancers. Of course, one might conclude that all of our endometrial cancers are in the twenty-three (14.2 per cent) cases on whom follow-up was impossible. There is no evidence to support this, but the search for

Tumors of the Gall Bladder

I. Cholesterol Pseudo-Polyps

JAMES MYHRE, M.D.

Minneapolis, Minnesota

IN A PERIOD of seven years, thirty patients with an x-ray diagnosis of papilloma of the gall bladder by cholecystogram have been accumulated. Seven of the patients have been operated upon and one patient autopsied. In these eight, a pseudo-polyp has been found and not a neoplasm as the x-ray term suggested.

The cholecystographic diagnosis was made on finding a filling defect attached to the wall of the gall bladder which did not change position on the patient's assuming an upright position. A minimum of two separate x-ray studies of the gall bladder were made to be certain of a lesion.

In all instances, anatomic verification of the filling defect in the gall bladder x-ray was found. In all eight of the patients, a true neoplasm or a papilloma or adenoma was not found. The findings in seven patients were described by the pathologist as cholesterosis, or actually single or multiple cholesterol polyps. One of these seven had associated small gallstones. One was simply a large gallstone apparently floating, without any other lesions. This gall stone had increased in size over a two-year period of observation, and it seemed very obvious to all concerned that it was a gall-bladder tumor which had grown. The gall stone was asymptomatic. Of the seven with the cholesterosis, two had symptoms strongly suggestive of gall-bladder disease, two had symptoms compatible with gall-bladder disease and three had no symptoms suggestive of gall-bladder abnormality.

Grossly, the cholesterol polyp is a large localized collection of lipid material in a villus of the gall bladder resulting in a papillomatous growth. They are generally multiple and one to five millimeters in diameter. They are easily detached as they are often connected to the wall of the gall bladder by a very fine pedicle, and one can easily

visualize their breaking off to becoming the nidus for gallstones.

Microscopically, one finds in the submucosa a localized collection of foam-like cells which are macrophages with ingested fatty material. This, if the lesions are small enough and diffuse enough, makes a "strawberry" gall bladder. If one of the strawberry lesions becomes large enough, a cholesterol polyp results.

This lesion has been popularly and inaccurately called a papilloma by x-ray description. This term suggests a true neoplasm or epithelial growth which, of course, it is not. Kirklin¹ found an 8.5 per cent incidence of papilloma of the gall bladder in 17,000 surgically removed gall bladders. Gross or histologic pathology was not described in his multiple publications on the subject but, judging from the photographs, he apparently was using the term papilloma for a localized polypoid collection of lipid material, or a cholesterol pseudo-polyp. It is from this report that a papilloma of the gall bladder has received the popular supposition of being fairly common, and is the basis for confusion in the literature. Modern-day pathologists are unable to include a cholesterol polyp as a true neoplasm; therefore, we now find that a papilloma or true polyp of the gall bladder is a rare lesion. In fact, in 1936 Kerr and Lendrum² accepted only seven cases of true papilloma of the gall bladder by rigid criteria. Kane³ found an incidence of 0.4 per cent in 2,000 surgical specimens.

Only a few authors have found evidence supporting a possible relationship between adenomas of the gall bladder and carcinoma, and that evidence is not at all convincing. Phillips⁴ reported an adenocarcinoma of the gall bladder in which there was a papilloma in another area of the organ. Lauritzen⁵ reported a case in which a gall bladder containing a papilloma was removed, and a year later the patient had a carcinoma of the common bile duct. Shepard et al⁶ found a case

Dr. Myhre is Clinical Assistant Professor of Medicine, University of Minnesota Medical School.

Fig. 1. (*above*) Cholecystogram showing filling defect near the fundus, diagnosed and diagnosed as a papilloma and found in surgical specimen (*below*) to be two cholesterol pseudo-polyps.

Fig. 2. Cholecystogram (*above*) showing filling defect in the body of the gall bladder, diagnosed as papilloma, and surgical gross specimen (*below*), showing one large and one small cholesterol pseudo-polyp.

of adenocarcinoma (Brody grade one) in a polyp of the gall bladder. Kerr and Lendrum² report three cases of carcinoma in which there was an associated papilloma formation. Tabah and McNeer⁷ present the best evidence in reporting four cases of true papilloma of the gall bladder in three of which there was carcinoma *in situ*.

Bockus⁸ considers cholesterosis as giving symptoms. It seems likely that the cholesterosis leads to small biliary calculi and eventually the clinical picture of cholelithiasis, choledocholithiasis and cholecystitis.

A diagnosis of cholelithiasis having been made, it is felt that the patient should, everything else being equal, have the gall bladder removed before complications occur. Approximately one-third of pa-

tients with cholesterol pseudo-polyps have an associated cholelithiasis.⁹ It should be remembered in considering this, that two-thirds or more of the cases of carcinoma of the gall bladder have an associated cholelithiasis. It seems impossible to tell whether or not the mucosal lesion is a cholesterol polyp or a true papilloma or adenoma. By the same token, it would seem impossible to know whether or not the lesion is an early cancer of the gall bladder, and it is only with such a lesion that carcinoma of the gall bladder seems curable.

From the surgical viewpoint, when there is a filling defect of the gall bladder, cholecystectomy should be strongly considered. A cholesterol pseudo-polyp could be the correct diagnosis or there could be, and frequently is, associated cholelithia-

Fig. 3. Cholecystogram (*above*) showing lesion diagnosed as a papilloma, but in a surgical specimen (*below*) a cholesterol pseudo-polyp was found instead of a neoplasm.

Fig. 4. Gall-bladder x-ray (*above*) showing multiple filling defects diagnosed as multiple papilloma or polyposis, but surgical specimen (*below*) shows multiple cholesterol pseudo-polyps.

sis. There might be a true mucosal lesion and, though not proven, possible malignant degeneration, or the patient might have an early curable carcinoma of the gall bladder. Cholesterosis, or the isolated lesion called a papilloma, is frequently symptomatic.

Surely, no such conclusion can be drawn from these data, and insufficient knowledge exists in the literature to permit a definite conclusion. It might well be that more conservatism is indicated. Prescribing the usual gall-bladder diet, perhaps with bile salts, and following these lesions by repeated x-ray examination, might be profitable, and does not seem unreasonable. The effect of a very low fat diet would be most interesting to note.

Summary

Eight patients with a cholecystographic diagnosis of papilloma of the gall bladder were operated

upon or autopsied. A morphologic lesion was confirmed at surgery, but the anticipated epithelial papilloma or true adenoma was not found as anticipated. Instead, a cholesterol or pseudo-polyp was found in seven patients and a common gallstone in one patient. One must remember that the x-ray diagnosis of papilloma is purely a morphologic, not a histologic, diagnosis, and hence does not mean a neoplasm. In fact, the x-ray diagnosis of papilloma appears to be quite accurate in revealing a cholesterol pseudo-polyp. A filling defect suggestive of a papilloma or adenoma in a cholecystographic study, as interpreted by the surgeon, should be removed. Cholesterosis is frequently symptomatic and associated with cholelithiasis, and this would lend support to the decision to remove the gall bladder. However, the chance that a true papilloma is present is apparently very slim, and malignant degeneration seems even remote.

Fig. 5. Single papilloma diagnosed by cholecystogram (above) which, on surgical specimen (below) was a polypoid collection of macrophages containing a lipoid material or a cholesterol pseudo-polyp.

Fig. 6. (above) Typical histologic section of a cholesterol pseudo-polyp showing the characteristic thin pedicle and the large macrophages with ingested lipoid material or foam cells on the right.

Fig. 7. (below) High power magnification of a cholesterol pseudo-polyp. Note the normal gall-bladder mucosa on both sides, and in the center the macrophages with typical foamy or fatty cytoplasm.

The chance of finding an early operable carcinoma of the gall bladder seems exceedingly remote. The diagnostic term papilloma should not be used in describing a roentgenographic lesion.

MONEY IS ELUSIVE

Money is such an elusive thing—not only to get and keep, but even to keep track of. New reports say that Americans owe more than ever before, some 700 billion dollars in public and private debt—up a whopping 294 billion since World War II ended. But along with this, the reports say also that Americans are richer than ever before—they own, in public and private wealth,

some 1½ trillion dollars' worth of property, and this year their income will be 340 billion dollars. But still another report says that all this doesn't mean what it seems to mean; that rising taxes and inflation since 1939 have made \$6,122 now equal actually to only \$3,000 then. However you slice it, money, it seems, is still purely relative.—*B. C. Enquirer*, October 24, 1956.

Case Presentation

Obstetrical Hemorrhage Into the Broad Ligament

CORNELIUS A. SAFFERT, M.D.

New Ulm, Minnesota

POST-PARTUM hemorrhage is usually obvious. However, it may be concealed and present a greater diagnostic and therapeutic problem. Post-partum hemorrhage may also present itself as a combination of external and concealed bleeding as the case to be presented shows.

Case Report

Mrs. L. B., a thirty-nine-year-old multipara, was at term and a frank breech was presenting.

Past History:—Her first baby was born February 11, 1947, when she was aged twenty-nine. During this pregnancy the blood pressure ranged from 130/88 to 160/86. All urinalyses were normal. Her second delivery was January 27, 1948. This was a 7 pound 4½ ounce footling breech extraction with a moderately severe postpartum hemorrhage. Blood pressure range during this pregnancy was from 134/66 to 142/74. An appendectomy was done on January 6, 1949. Exploration then showed a congenital absence of the right tube and ovary, and a severely ptosed right kidney. Her third delivery on August 9, 1951, was a footling breech with a 5 pound 14½ ounce baby. During this pregnancy all urinalyses were normal. The blood pressure varied between 128/66 and 170/84. On October 5, 1951 a dilatation and curettage was done for abnormal bleeding due to subinvolution of the uterus. At the same time an abscess of the left breast was incised and drained. On July 10, 1953 a dilatation and curettage was done for a missed abortion. Following this she had amenorrhea for eight months and then resumed regular periods.

Present Pregnancy:—Her last menses was on December 16, 1954. On March 8, 1955 her blood pressure was 120/64. The urine had a foul odor, albumin was 3+, and the sediment showed mixed bacteria 4+. On March 29 the blood pressure was 136/70. The urine albumin was 4+, and the sediment showed a marked pyuria and a large number of mixed bacteria. She had marked varicose veins of the left leg with two sites of superficial thrombosis in the left thigh. On April 7 the urine was negative except for an occasional finely granular cast. The pyuria had cleared under Gantrisin®. Blood pressure and urinalyses remained normal

through May, June, and July. She was next seen on August 1 with leg edema of two weeks' duration. Her weight was 142 pounds, a gain of twenty-eight pounds in six months. The heart was normal, and the blood pressure was 122/56. The urine showed 2+ albumin and a large number of coarse granular casts. She was placed on a low sodium diet, was given 1 cc Salyrgan Theophylline intravenously, and one tablet of Neohydrin daily was prescribed. On August 9 the edema was less, and the weight was 139 pounds. Urinalysis showed albumin 1+ and ten to twelve fine and coarse granular casts per low power field. The above treatment was continued. On August 16 the weight was 136¾ pounds, blood pressure was 124/70, and the urine sediment still showed numerous coarse granular casts. On August 24 her weight was 134½ pounds and urinalysis was normal. There had been no leg edema for several days. A diagnosis of breech presentation was made. On August 30 there was no edema, the weight was 134 pounds, and the blood pressure and urinalysis were normal. On September 13 the weight was 133 pounds, the blood pressure was 144/76, and the urinalysis was normal. The cervix was ripe, and a frank breech presented. Pelvic measurements were normal. The patient was blood Group A, Rh positive.

Her membranes ruptured at home at 10:45 a.m. on Sept. 14, 1955. There were no contractions present. She entered Loretto Hospital at 11:05 a.m. Her previous labors had all been very rapid. A sterile pelvic examination at 12:30 p.m. substantiated the diagnosis of a frank breech presentation. At 1:30 p.m. with the contractions still very irregular and feeble, she was given a single dose of Pitocin, minims 2, and shortly went into active labor. At 2 p.m. the cervix was 4-fingers dilated, and the frank breech was stationed at the spines. She was catheterized, and a pudendal block of Novocaine with Wydase was done. The breech was allowed to descend to the vulva spontaneously. When there was definite bulging, a wide left lateral episiotomy was done. A hooked finger was put into the baby's groin for traction. Supplementary Trilene anesthesia was given. The impacted breech was easily broken up, and both feet and legs delivered. A routine breech extraction was done with minimal difficulty and without undue haste, aided by previous relaxation and the wide episiotomy. The head was easily delivered by a Mauriceau maneuver. A male baby was born at 2:15 p.m., weighed 8 pounds, 10 ounces, and breathed spontaneously. At 2:40 p.m. the placenta still had not separated and resisted efforts at expression. After changing to

Presented at the annual meeting of the Southern Minnesota Medical Association, New Ulm, Minnesota, September 10, 1956.

sterile gloves the uterine cavity was explored. The placenta was firmly adherent to the uterine wall. Manual removal of the placenta was done using the sides of the fingers to develop a cleavage plane. Examination of the placenta showed it to be apparently intact. The episiotomy was repaired. At this time the general condition of the patient was poor. She was retching and appeared to be in impending shock. The blood pressure was 84/64. Pitocin 1 cc had been given immediately after the birth of the baby. Ergotrate 1 cc intravenously had been given immediately after the manual removal of the placenta had been completed. The blood loss was estimated at 300 cc. The uterus was firmly contracted. The patient was returned to her room at 3 p.m., still nauseated.

At 3:30 p.m. the blood pressure was 84/64, and the pulse rate was 126. The skin was cold and slightly clammy. An intravenous infusion of 5 per cent glucose in saline was started at this time, and was replaced with 1 pint of compatible Group A, Rh positive blood at 4:10 p.m. At 5:15 p.m. the blood pressure was 98/80. At 6:00 p.m. she was no longer nauseated and her skin was warm. She had saturated 3 pads. Another 500 cc of bank blood was given. At 6:40 p.m. her blood pressure was 120/80, her pulse was 104 and the uterus firm. The transfusions were completed at 7:00 p.m. At 7:10 p.m. the patient had a frank uterine hemorrhage, and the blood pressure dropped to 82/70. The patient was again in shock but conscious and rational throughout this time. 250 cc of Gentran was given intravenously, and 500 cc of saline with 1 cc of Pitocin added was started in another vein. Dr. P. J. Kitzberger was called as consultant. One ampoule of Wyamine was given. The third pint of blood was started as soon as it was available at 8:00 p.m. The uterus was 2 fingers above the umbilicus and was relaxed, but contracted with massage and Pitocin, only to relax again. An interesting observation was that shock deepened after each attempt at massage of the uterus. The patient continued to bleed *per vaginam*. At 8:45 p.m. the blood pressure was 50/20 and the pulse rate 120. A soft doughy mass was starting to form in the left lower quadrant. The bladder was catheterized, and the urine was normal, thus ruling out bladder injury. 600 cc of compatible fresh blood was taken from the husband, and transfused into the patient. At 9:30 p.m. the mass in the left lower quadrant was definitely growing, and the blood pressure was still 50/20. We felt that there was continuing bleeding into the left broad ligament and that emergency surgery was indicated despite the continuing shock. A local surgeon was called into consultation, and all agreed on emergency surgery despite the desperate condition of the patient.

Surgery was started under local anesthesia at 10:45 p.m. with the blood pressure at 46/0. An additional 1,000 cc of bank blood was given during surgery with forced pumping. The abdomen was opened. There was no free blood in the abdominal cavity. There was a large hematoma in the left broad ligament which dissected upward retroperitoneally. The previously known congenital absence of the right tube and ovary

was again noted. There was no free perforation of the uterus into the abdominal cavity. An emergency subtotal hysterectomy was done starting on the left side. As soon as the source of bleeding into the left broad ligament was clamped there was a noticeable improvement in the general condition of the patient, similar to that seen in surgery for ruptured ectopic pregnancy. Sodium pentothal was started as supplemental anesthesia. The hematoma of the left broad ligament and retroperitoneal area was evacuated. Careful attention had been paid to avoid injury to the ureters. After being sure that hemostasis was complete, the abdomen was closed in layers. The immediate postoperative condition of the patient was noticeably better than her preoperative condition. The transfusions were completed before she was returned to her room. By 1:30 a.m. her pulse was 96 and blood pressure was stable at 122/80.

The pathologic report received from Robert Hebbel, M.D., of the University of Minnesota Department of Pathology is as follows: "The uterus is about 15x15x10 cm. over-all. The walls are greatly thickened and the lining is roughened and hemorrhagic through most of the cavity. The attached left tube is 5 cm. long, and the ovary is 3x3x1 cm. Multiple gross sections of the uterine wall show no abnormality of the muscle. Microscopic sections show placental tissue intimately involving the muscular wall." These findings are in keeping with a diagnosis of placenta accreta.

The patient made a relatively smooth postoperative recovery. On several occasions, always at night, she had attacks of left lumbar pain lasting up to two and one-half hours. The last attack was two days before discharge from the hospital on September 23, 1955. After leaving the hospital she developed a left uretero-cervical fistula due to injury to the left ureter at the time of the emergency hysterectomy. She was referred to Mayo Clinic for treatment of this condition. Treatment there was complicated by the fact that the severely ptosed right kidney contained a large calculus, making reconstructive surgery on the left ureter mandatory in an attempt to save her better kidney. She is still under observation at the Mayo Clinic at this time.

Comment

Quoting and taking excerpts from "Obstetric Practise" by Speert and Guttmacher we find the following: (McGraw-Hill Co., New York, 1956) "In rare cases placental separation fails to occur because of a deficiency or absence of the maternal decidua at the placental site, with the resultant invasion of the myometrium by the chorionic villi. This condition is known as placenta accreta. Not only does it prevent spontaneous separation of the placenta, but it resists attempts at manual removal as well, because a cleavage plane between the placenta and uterus can not be established. Placenta

accreta should be suspected in cases of retained placenta if careful attempts at manual removal prove unsuccessful because of the operator's inability to peel the placenta from the uterine wall. The diagnosis can only be proved on microscopic examination of the excised uterus, which reveals an absence of decidua vera, the chorionic villi lying in direct contact with the myometrium. Placenta accreta is best treated by immediate hysterectomy."

"In contrast to the external bleeding that occurs from lacerations of the cervix, the major hemorrhage from tears of the corpus is usually concealed, either in the peritoneal cavity, in the broad ligaments, or under the bladder peritoneum. Traumatic rupture of the uterus may be caused inadvertently by internal podalic version, the obstetric forceps, excessive force applied to the abdomen during the second stage, or manual removal of the placenta. The tear, usually occurring in the lateral walls of the lower segment, often extends into the uterine vessels. Both vaginal and intra-abdominal hemorrhage are common; the latter may be free into the peritoneal cavity or between the leaves of the broad ligament, where it creates a hematoma. Severe pain and tenderness in one of the lower quadrants of the abdomen is usual, although it was not present in the case reported. Shock appears quickly and deepens rapidly. Most ruptures of the intact uterus occur during delivery. The most significant sign is the

continuation of brisk hemorrhage from a well contracted uterus after the placenta has been delivered. The treatment of uterine rupture is immediate laparotomy. Transfusions should be started while preparations are being made for operation, even in the absence of shock. In most instances a subtotal hysterectomy is performed, but if the rupture extends upward from a cervical laceration total hysterectomy may be necessary to control bleeding. The proximity of the ureter should be kept in mind and its ligation carefully avoided in cases of hematoma of the broad ligament."

Summary

The case reported is that of a patient who had a bad obstetrical past history. During the present pregnancy she had pre-eclampsia. She had a frank breech delivery complicated by manual removal of a retained placenta accreta. This resulted in perforation of the left lower uterine segment with dissecting hemorrhage into the left broad ligament, and delayed external postpartum hemorrhage, causing exsanguination and prolonged shock. A growing mass developed in the left lower quadrant. An interesting observation was a temporary deepening of the shock following each palpation or attempted massage of the uterus. Emergency hysterectomy was done with injury to the left ureter.

STEM PESSARIES RULED DANGEROUS

The Food and Drug Administration said today that stem pessaries are dangerous and should be removed from the market at once. In a formal policy statement published in the Federal Register, FDA concluded that "stem-type and wing-type intracervical and intrauterine pessaries are dangerous to health, and regardless of their labeling, may be shown to be misbranded." Distributors were advised by FDA to remove such articles from the interstate market at once, with a strong hint that otherwise court proceedings would be instituted.

FDA emphasized, however, that its action does not apply to other types of pessaries which are safely used following surgery and for supportive purposes.

The policy statement declares that it is now the consensus of medical opinion among experts qualified by scientific training and experience to evaluate the safety

of such devices that stem-type and wing-type intracervical and intrauterine pessaries are dangerous for use under any form of labeling and serve no useful purpose.

Dr. Albert H. Holland, Jr., Medical Director of the Food and Drug Administration, said that such devices have been used as contraceptives for many years but are not reliable for preventing pregnancy. He said the pessaries have been labeled for use only under medical supervision since 1941 and that the decision to institute legal action against them was reached as a result of a recent medical survey in which 92 per cent of the experts consulted regarded these devices as dangerous for use under any conditions. These opinions were supported by many known cases of injuries, infections, cancer, and pregnancy associated with the use of such pessaries.

Current Concepts of Osteoporosis

PAUL D. REDLEAF, M.D.

Minneapolis, Minnesota

OSTEOPOROSIS, the commonest systemic disease of the skeleton,^{8,100} has generally been defined as a decrease in bony tissue in which the primary disturbance is lack of bone matrix formation.^{3,85}

This paper will consider etiology, diagnosis, and clinical features of osteoporosis largely as background against which therapeutic measures can be discussed. The author believes that therapeutic progress will be based on new knowledge of the biochemistry and physiology of bone. For this reason, recent studies on the composition of bone and the mechanism of calcification will be presented.

Classification

The following table, modified after Albright and Reifenstein,⁸ presents a useful means of classifying osteoporosis. Separation of osteoblastic function from the quality or amount of the matrix is arbitrary.^{37,81} The existence of a "defect unknown" group indicates the need for further study.

I. Defect in Osteoblasts

- A. Loss of stress and strain (e.g. immobilization, poliomyelitis, old age).
- B. Estrogen lack.
 1. Postmenopausal state.
 2. Congenital hypoenestrogenism (e.g. ovarian agenesis, panhypopituitarism, the syndrome of isolated pituitary FSH deficit).
- C. Congenital osteoblastic defect (e.g. osteogenesis imperfecta).

II. Defect in Matrix

- A. Loss of androgen.
 1. Eunuchoidism.
 2. ? Senile osteoporosis.
- B. Loss of protein.
 1. Malnutrition (e.g. hyperthyroidism, poorly-controlled long-standing diabetes mellitus, nephrosis).
 2. Hypovitaminosis C.
 3. Cushing's syndrome.
 4. The "alarm reaction."

III. Defect unknown

- A. Acromegaly.
- B. Idiopathic osteoporosis.

Clinical Aspects of Osteoporosis

Osteoporosis may occur at any age, but reaches a peak incidence between the ages of sixty and sixty-five years.¹² Females are affected four times as frequently as males,^{10,21,26,74} female preponderance being even higher among younger patients.⁹⁹

The commonest symptom of osteoporosis is low back pain. Extensive vertebral collapse may cause a loss of height. With the exception of the spine, osteoporotic bones are neither tender nor painful.¹⁶

Diagnosis is based upon characteristic radiologic findings coupled with normal laboratory values for serum calcium, phosphorus, and alkaline phosphatase.

Bony demineralization is most commonly noted in the spine upon radiologic examination. Compression fractures may be seen; intervertebral discs may balloon into the central portion of the vertebral bodies producing typical "codfish vertebrae." The pelvis and ribs are frequently demineralized. The skull is rarely involved except in far-advanced disease; demineralization here is most characteristically localized to the frontal and parietal bones.⁹⁹ The remainder of the skeleton is less often affected,¹⁰⁰ and the lamina dura are preserved.

Correlation of radiologic findings with the severity of symptoms is exceedingly poor.⁸³ Conversely, while therapy may produce striking symptomatic improvement and appreciable increases in total body calcium, increase in bone density is exceptional.^{35,95} Correlation of x-ray changes with data on calcium balance depends on the distribution of the osteoporotic process. Thus relatively small calcium losses may accompany the evolution of osteoporosis in an extremity in poliomyelitis,¹⁰⁵ whereas up to 60 per cent of the total body calcium may be lost without radiologic evidence of osteoporosis in the spine.²⁷ New objective tech-

Dr. Redleaf is Public Health Service Research Fellow, Department of Medicine, University of Minnesota Hospitals.

niques for evaluation of bone density⁶⁷ may possibly increase the value of future radiologic studies.

The usually normal laboratory values for serum calcium, phosphorus, and alkaline phosphatase support the interpretation that osteoporosis is a disease of tissue rather than calcium metabolism. However, hypercalcemia may occur during the rapidly progressive phase of osteoporosis, for example during the immobilization of young patients or those with Paget's disease. Whereas most investigators have found serum phosphorus normal,^{12,25} Albright, Reifstein, and Forbes have noted a slight but significant elevation of serum phosphorus, which falls with successful treatment.^{8,9} Borderline elevation of alkaline phosphatase may reflect osteoblastic repair of multiple fractures;⁸¹ greatly elevated alkaline phosphatase levels make uncomplicated osteoporosis unlikely.¹⁰⁶

The normal decrease in urinary phosphorus following intravenous calcium may help distinguish osteoporosis from hyperparathyroidism.⁵⁴ Study of urinary calcium excretion following intravenous calcium gluconate has shown a subnormal calcium retention in patients with osteoporosis.⁹³ Although this test does not distinguish osteoporosis from all other osteolytic lesions, it has provided an objective measurement of improvement during the course of successful therapy.¹⁰² Accumulation of additional data defining the normal range of calcium retention during this procedure may make it possible to suggest the diagnosis of incipient osteoporosis prior to the stage of overt roentgenologic demineralization.

Therapeutic Measures

I. Dietary Management

A. Calcium

1. *Effects.*—Many investigators have demonstrated conversion of negative to positive calcium balance in osteoporosis,^{2,12,17,19,25,81,96,97,98} and in normal persons^{24,69,77} by high calcium intake. Three possible mechanisms have been suggested.⁸ First, an increase in available calcium and phosphorus may stimulate osteoblastic activity. Slight nitrogen retention has been observed during metabolic periods on intravenous calcium administration.¹⁹ However, this observation has been made only on a few subjects; furthermore, the assumption that a positive nitrogen balance indicates formation of bone matrix is questionable. Secondly, osteopathies attributed to lack of cal-

cium and phosphorus may really be due to protein starvation. However, this concept hardly accounts for the observed calcium retention when supplementary calcium is added to a diet of constant protein content. Thirdly, increased availability of calcium and phosphorus may decrease resorption of bone. The prevention of osteitis fibrosa generalisata in hyperparathyroidism by high dietary calcium intake⁸ further suggests that resorption of the bony mineral reservoir may be checked if other sources of calcium are readily available.

2. *Present uncertainties.*—Nevertheless, the precise therapeutic status of calcium supplements remains controversial. It is convenient to digress at this point and consider four factors responsible for current uncertainty. First, on theoretical grounds, osteoporosis is a disorder of tissue metabolism rather than calcium metabolism. The classification presented demonstrates the association of osteoporosis with conditions causing decreased synthesis or increased catabolism of protein, whereas osteomalacia (or rickets) is the usual result of calcium or phosphorus deficiency.

Histologic studies, too, are difficult to harmonize with the beneficial effects of calcium supplements. Osteoporotic bones contain a decreased number of osteoblasts or histochemically abnormal osteoblasts;⁸¹ trabeculae are sparse and thin, but there is no microscopic evidence that osteoclastic activity is abnormally increased.^{14,96} That matrix which is laid down is normally calcified.^{3,81}

While direct evidence that osteoporosis is due to inadequate matrix formation has not been presented,³⁸³ the characteristic histology, laboratory chemical findings, and clinical picture make this hypothesis attractive. Convincing evidence that supplementary dietary calcium either stimulates osteoblastic activity and additional matrix formation or inhibits bone resorption (thereby compensating for decreased bone formation) is lacking. We lack a convenient laboratory index of bone resorption; further studies of the turnover of bone mineral utilizing isotope techniques or strontium may clarify the mechanism involved.

Secondly, low calcium intake has not been linked etiologically to the development of osteoporosis, although Groen⁴² (quoted by Snapper¹⁰⁰) offered the clinical impression that the disorder occurs more frequently among food fadists on low calcium intakes. Unfortunately, retrospective stud-

ies of dietary intake are not obtainable once the diagnosis of osteoporosis has been established and therapy instituted. Nor have controlled studies of the earlier phases of the disorder, before x-ray demineralization is evident, been obtainable.

Poor calcium absorption, in contrast to poor intake, has been implicated in the osteoporosis of childhood nephrosis; here, however, the negative balance for calcium parallels a low serum albumin and negative nitrogen balance.³⁴

Bone radiolucency has been produced in young rats by diets poor in calcium phosphate salts.⁴¹ The use of the term "osteoporosis" rather than "osteomalacia" for the syndrome observed is not adequately justified, however.

A third source of confusion on the use of calcium supplements in osteoporosis is our inadequate knowledge of normal calcium requirements. According to the literature,¹ the normal requirement is approximately 800 mgm. daily. However, adaptation to prolonged low dietary calcium occurs, and intakes of 100 to 200 mgm. are not incompatible with calcium equilibrium and apparent good health.⁴⁹ Considerable individual variability in this capacity to adapt to decreased intakes probably exists.⁷⁷ These considerations indicate the need for caution in extrapolating short-term balance data following changes in calcium intake.

Variability in calcium absorption is another factor to be considered in studies on calcium intake. Some persons absorb large amounts of dietary calcium if such is provided; most persons absorb but little calcium no matter how much is eaten, unless the bones have a need for it.⁵³ Such variations in absorption could account for the variable correlation of urinary calcium excretion with calcium intake.^{52,55,61}

The influence of age on dietary requirements is not clear. Animal experiments^{58,59,71} and clinical studies^{1,87} have suggested an increased calcium requirement in the elderly, but others^{24,61,78} have not confirmed this.

Factors influencing calcium absorption include achlorhydria, protein intake, and other dietary constituents. Meulengracht noted achlorhydria in 42 per cent of his patients with osteoporosis,⁷⁴ but animal studies have demonstrated that alkalization of the gastric juice merely increases fecal calcium at the expense of urinary calcium without altering calcium retention.⁹⁴ Human calcium absorption directly parallels protein intake.^{63,70,82} Dietary vegetable content, ingested acids, keto-

genic diets, and dietary calcium/phosphate ratio may also influence calcium absorption.⁶¹

Fourth, uncertainty over the therapeutic role of calcium supplements arises from the balance studies thus far conducted in osteoporosis. In these studies, diet is generally maintained constant while the additive effects of steroids or other agents is determined. The author has encountered no data analyzing the effect of calcium supplements given after a base-line period of optimal hormonal therapy.

3. *Recommended Regimen.* — Albright and Reifenstein assert that "since osteoporosis is not a disease of calcium and phosphorus metabolism, excessively high intakes of these minerals and vitamin D are probably not indicated."^{8,85} Others,^{81,98} citing the positive calcium balance produced by dietary measures alone, recommend 1.5 to 2.0 grams daily. At about this level a ceiling is reached,⁹⁸ above which additional calcium intake is quantitatively excreted.

B. Phosphorus

Uncertainty over optimal dietary phosphorus in osteoporosis parallels our confusion over calcium in therapy. Phosphorus equilibrium is attained on intakes of 1000 to 2000 mgm. daily according to the literature.¹ Whether advanced age increases^{1,87} or decreases⁷⁸ requirements is uncertain. The effect of added phosphate on calcium absorption in normal persons is also uncertain.^{66,68} In osteoporosis, a decrease in phosphorus intake causes a decrease in estrogen-induced positive calcium balance,¹² and large doses of NaH_2PO_4 increase the retention of intravenous calcium.¹⁹

In practice, most clinicians feel that diets adequate in protein^{81,85} and calcium^{81,98} provide sufficient phosphorus.

C. Vitamin D

Since 10,000 to 50,000 units of vitamin D daily may increase mineral retention in patients without overt hypovitaminosis on optimal diets,⁹⁶ some clinicians^{13,81,96} recommend this measure routinely, particularly for patients confined indoors.

II. Other Minerals

A. Strontium

Because strontium resembles calcium in its physical and chemical properties, Shorr and Carter have investigated its effect in osteoporosis.^{27,96,97,98}

After maximal calcium retention has been achieved through the use of high calcium intake, addition of 1.7 grams of strontium daily approximately doubled the total calcium plus strontium retention.⁹⁶ Additional tristrontium phosphate is retained without decreasing calcium salt retention. The additive effect of strontium in augmenting "lime salt" retention is further increased by vitamin D, estrogen, and/or androgen therapy.

Clinically, subjective improvement corresponded better with the combined strontium and calcium retention than with the calcium retention alone, according to Shorr and Carter.⁹⁸ Although strontium is not a normal dietary constituent, it is apparently nontoxic for long periods in the dosage indicated.^{28,98}

These studies, like those on calcium supplements, apparently indicate that mineral retention can occur in osteoporosis without significant nitrogen retention.⁹⁷ Further study on the clinical use of strontium is indicated; in particular, its effect when added to a base line optimal hormonal regimen is unknown.

B. Copper

Copper deficiency can produce osteoporosis in dogs.¹⁸ To date, this finding has not been related to human osteoporosis. Further studies on the relation of copper to ascorbic acid metabolism are needed.

III. Endocrine Therapy

The association of osteoporosis with gonadal insufficiency provided the initial rationale for the therapeutic trial of estrogens and androgens. The clinical observation of female preponderance in osteoporosis supports this hypothesis; the menopause occurs earlier in life than the cessation of Leydig cell activity, and thus gonadal deficits may occur earlier and more frequently in the female.⁴ Finally, one would expect hormonal therapy to be most successful when an actual deficiency exists; indeed those "idiopathic" cases of osteoporosis unbenefited by gonadal steroids^{8,13} are characteristically normal endocrinologically.

A. Estrogen

The effect of estrogen on the skeleton has been investigated in osteoporosis, in normal humans, and in experimental animals.

1. *Effects in osteoporosis.*—In postmenopausal and in senile osteoporosis, estrogen administration

causes a decrease in both fecal and urinary excretion of calcium and phosphorus, occurring in about six days, reaching a maximum after one month, and persisting more than a month following hormone withdrawal.^{8,12} Urinary nitrogen excretion is but transiently decreased. An additive effect on calcium retention is demonstrable in androgen-treated patients. Qualitatively similar estrogen effects are noted on calcium intakes ranging from 200 mgm.⁸ to 2000 mgm.⁹⁶ daily; further quantitative studies are needed. Symptomatic improvement generally parallels calcium retention.^{8,81,98}

2. *Effects in normal persons.*—To what extent the effects of estrogen in osteoporosis depend on the existence of gonadal insufficiency is not clear. Retention of calcium,¹⁹ phosphorus,^{19,62} and nitrogen⁶² has been noted in normal females given estrogen. The effects of estrogen in elderly males without osteoporosis were qualitatively similar but of lesser magnitude than in patients with senile osteoporosis.²⁵ On the other hand, the normal positive calcium balance in adolescent girls was decreased by estrogen administration.⁵⁷

3. *Effects in animals.*—The results of estrogen administration to experimental animals shed little light on the mechanism of estrogen action in human osteoporosis. This is largely because effects vary according to the species and dosage employed as well as the age and endocrinologic status of the animal. Birds^{22,64,65,79,80} respond with marked endosteal bone proliferation, eventually obliterating the marrow spaces, correlated with a rise in nondiffusible serum calcium levels. Similar changes occur in untreated female pigeons during the egg-laying cycle; endosteal bone apparently serves as a reservoir of readily available calcium for egg shell formation. In mice, increased endosteal bone formation and decreased bone resorption were noted;^{8,103} however, when estrogen was begun in older mice, the resorptive process was accentuated rather than inhibited.⁴⁰ Interestingly, the mouse skeleton is not a homogeneous target organ; estrogen produced bony proliferation of the femur with concomitant dissolution of pelvic bones.³⁹ In young rats estrogen interferes with endochondral ossification by inhibiting resorption of cartilage matrix and new bone.¹⁰³ Estrogen-treated castrates show increased endosteal osteoid production in response to experimental fractures,⁸⁴

and serum calcium elevations have been noted.⁸⁷ In hamsters, guinea pigs, rabbits, dogs, and cats there is apparently no specific estrogen effect upon bone production.¹⁰³

4. *Therapeutic regimen.*—Natural or synthetic estrogens are equally effective in the treatment of osteoporosis. Any of the following preparations give equivalent results:⁸

(a) Diethylstilbestrol, 0.5 to 1.0 mg., daily, by mouth.

(b) Estrone sulfate, 2.5 to 3.75 mg., daily, by mouth.

(c) Estradiol benzoate, 1.66 to 3.32 mg., three times weekly, intramuscularly.

(d) Estradiol dipropionate, 5 mg., once weekly, intramuscularly.

Higher doses apparently confer no added benefit.^{8,12,48}

To avoid excessive uterine bleeding and possible carcinogenic effects, estrogen should be withdrawn in females at intervals of four to six weeks for a period of seven to ten days.⁸ Alternatively, progesterone may be administered for five days in daily intramuscular doses of 5 mg., or in the form of anhydrohydroxy progesterone, 40 to 60 mgm. daily by mouth.⁸ Examination of the vaginal smear twice yearly³⁸ and periodic pelvic examinations are additional safeguards. Salt restriction may be necessary to prevent edema.

B. Progesterone

Progesterone is used in osteoporosis only as a means of preventing endometrial hyperplasia. Combined with estrogen or given alone in amounts up to 100 mg., it is without effect on metabolic balances.⁸

C. Androgen

1. *Metabolic effects.*—Administration of androgen to patients with osteoporosis causes a decrease in both fecal and urinary loss of calcium and phosphorus. The effect occurs slowly and persists long. In contrast to estrogen, androgen administration causes a prolonged decrease in urinary nitrogen, and a positive nitrogen balance is attained. Following hormone withdrawal, calcium retention persists longer than phosphorus or nitrogen retention.⁸

2. *Mechanism of action.*—While the mode of action of androgen at the cellular level is not known, the benefit conferred on osteoporotic patients seems to reflect a general anabolic effect. Perhaps for this reason, androgen therapy has seemed more effective than estrogen in osteoporosis associated with excessive protein breakdown, i.e., Cushing's syndrome⁷ or thyrotoxicosis.⁶⁰ Adrenal biopsies of a patient with Cushing's disease revealed striking changes in the histochemical staining properties of the zona fasciculata, correlated with testosterone therapy.⁴ The suggestion that the action of androgen involves inhibition of production of anti-anabolic adrenal steroids awaits confirmation by more precise analyses of adrenal corticoids. An additional mechanism of action must also be present to account for the nitrogen and phosphorus retention in patients with Addison's disease on androgen therapy.⁴

3. *Effects on osteogenesis.*—Whereas androgen prevents excessive osseous growth when administered to certain mammals receiving estrogen,⁴⁰ this effect is apparently species specific. A synergistic rather than antagonistic action with estrogen occurs in the pigeon,^{3,79} and "man apparently resemble the pigeon rather than the mouse in this regard."⁸

Although evidence from animal studies is difficult to apply and the direct evidence is insufficient, it seems probable that testosterone stimulates both endochondral and endosteal bone formation in man.³

4. *Therapeutic regimen.*—The following regimens have been recommended for androgen therapy of osteoporosis:⁸

a. Methyltestosterone, 10 to 20 mg., daily, by mouth.

b. Testosterone propionate, 10 to 25 mg., once weekly, intramuscularly.

c. Testosterone, 2-75 mg. pellets implanted subcutaneously every three or four months.

Doses exceeding 300 mg. of androgen monthly risk virilization of female patients⁸⁵ and increase the problem of salt retention and edema formation. Estrogen should be administered concurrently in males, for its synergistic effect on calcium retention, and to neutralize androgenic stimulation of the prostate.⁵⁶

D. ACTH and Adrenal Cortical Hormones

The osteoporosis and pathologic fractures of naturally occurring^{32,101} or iatrogenic^{31,37} Cushing's syndrome, and experimental data showing the deleterious effect of cortisone on mucopolysaccharide formation and on bone healing,²³ indicate the hazard involved when these agents are used in patients with osteoporosis. However, the usual rise in urinary calcium excretion produced by ACTH or cortisone³³ was not consistently duplicated by Hjorth and Dragsted.⁵⁰ These investigators concluded that short-term adrenal cortical hormone therapy was not absolutely contraindicated by the presence of osteoporosis if indicated for an acute concomitant disease process.

IV. Intravenous Albumin Therapy

The malnutrition often associated with osteoporosis, and the improved calcium absorption on high protein diets^{63,70,82} are adequate grounds for administration of liberal quantities of protein in osteoporosis.^{81,85} Nonetheless, oral albumin⁵ and casein hydrolysate⁸ have been without effect on the calcium balance of refractory patients.

The parallel fluctuations of calcium balance, serum albumin levels, and nitrogen absorption in childhood nephrosis³⁴ have suggested investigation of the therapeutic value of plasma transfusions and intravenous albumin in osteoporosis. Thus far these effects have been explored in isolated cases of idiopathic osteoporosis refractory to hormonal therapy,^{4,5,8,13} osteogenesis imperfecta,⁵ and postmenopausal osteoporosis.⁵ With elevation of serum albumin levels both diffusible and nondiffusible serum calcium rise, and urinary calcium excretion decreases.

The consistency of this relationship, the correlation of subjective improvement with measured calcium retention, and the paradoxical fall of urinary calcium despite elevation of serum diffusible calcium have suggested that intravenous albumin stimulates bone formation. The possibility has indeed been raised that serum albumin may be a transport form of bone matrix precursor;⁵ since similar effects follow intravenous globin administration,⁵ however, the specificity of this albumin effect is dubious. Paradoxically, alkaline phosphatase levels fall with albumin therapy; this may be a dilution phenomenon or related to the finding that albumin inhibits phosphatase activity *in vitro*.⁵

Since albumin administration promotes urinary

but not fecal conservation of calcium,⁵ its quantitative effect is probably smaller than that of the gonadal steroids. For this reason, and because of the expense and inconvenience of this mode of therapy, it deserves clinical consideration only when more conventional measures fail.

V. Orthopedic Measures

Immobilization relieves pain and, if the latter is severe, the physician may consider the use of corsets, braces, or even spinal fusion.⁴⁸ On the other hand, the removal of stress and strain withdraws an essential stimulus to osteoblastic activity.⁶ This relationship has been documented clinically in studies on osteoporosis in poliomyelitis.¹⁰⁵ During experimental immobilization, the consistent rise in serum calcium levels was prevented and calcium and nitrogen losses were halved by the use of oscillating rather than fixed beds.¹⁰⁴ Thus comparatively minor stresses and strains may inhibit skeletal dissolution.

VI. Therapy of Osteoporosis Summarized

When possible, the treatment of osteoporosis should be directed toward its cause.^{*} Thus, treatment of the underlying disorder will cause improvement of the osteoporosis of immobilization, Cushing's syndrome, hyperthyroidism, acromegaly, hypovitaminosis C, and malnutrition.

A balanced diet adequate in protein and calcium content should be provided, and vitamin D and strontium may be helpful adjuvant measures. Estrogen and androgen therapy are beneficial, particularly in postmenopausal and senile osteoporosis. Intravenous albumin deserves a trial in patients refractory to other measures. Use of orthopedic devices should be avoided whenever possible.

With such treatment one may expect relief of back pain and resumption of physical activity in the majority of cases within several weeks to months.

Current Concepts of the Process of Calcification

Much current research, as reflected by five recent Macy conferences,²⁹ has been devoted to problems in the structure and formation of bone. Although evidence thus acquired may lack immediate clinical application to the problem of osteoporosis, therapeutic progress ultimately rests on advances in our knowledge of bone metabolism.

The author will therefore attempt to summarize recent contributions to our understanding of bone physiology.

1. *Structure.*—Bone mineral comprises one third of the total bone mass. It is deposited diffusely as myriads of microcrystals measuring approximately $350\text{\AA} \times 300\text{\AA} \times 25\text{--}50\text{\AA}$ ⁸⁸ and giving an apatite lattice pattern on x-ray diffraction.^{44,76} These microcrystals are disposed in an orderly orientation⁸⁹ to correspond with fibrils of collagen, interspersed among which is an osseomucoid ground substance composed of complex mucopolysaccharides, including chondroitin sulfate.⁴⁴

The apatite lattice is a space arrangement rather than a formula. At least ten different formulas have been proposed for bone salt.¹⁵ At present the basic formula is conceived to be either hydroxyapatite ($3\text{Ca}_3(\text{PO}_4)_2 \cdot \text{Ca}(\text{OH})_2$) or hydrated tricalcium phosphate ($3\text{Ca}_3(\text{PO}_4)_2 \cdot \text{H}_2(\text{OH})_2$).³⁰ Disagreement over a correct formula may reflect the dynamic state in which bone salt exists and an inherent variability in its composition. This variability depends on two processes: absorption of additional calcium or phosphate on the apatite lattice, and substitution or surface binding of a great variety of ions.⁷⁶ Thus the composition of bone, within structural limits may vary in reflection of the composition of the blood as induced by diet.⁷⁶

Bone contains considerable CO_2 , approximately 5 per cent by weight. Whether this occurs as HCO_3^- or as $\text{CO}_3^{=}$ is not clear.⁷⁶ It has been suggested that $\text{CO}_3^{=}$ ions, by combining with the surfaces of bone crystals, cut off their growth, and thereby limit the crystals to the minute size which is responsible for the relatively large surface area in proportion to their mass.⁷³

2. *Formation of bone salt.* Much remains to be learned of the dynamics of calcification. The process was conceived originally as a precipitation of bone salt; however, no solubility product for bone has ever been demonstrated.⁵¹ Actually the concept of a solubility product is meaningless except in relation to a known and homogeneous solid phase of constant and comparatively simple ionic composition, which bone salt manifestly is not.⁷³ Furthermore, equilibrium is attained very slowly with hydroxyapatite, the results differ according to whether the state of saturation is approached from the direction of supersaturation

or undersaturation, and the relationships are influenced by such biologic factors as age and parathyroid function.⁷³

Within these limitations, it would seem that the product $(\text{HPO}_4=) \times (\text{Ca}^{++})$ represents a more reasonable precipitate than the fifth order reaction required by the product $(\text{Ca}^{++})^3 \times \text{PO}_4^{=}$.² In experimental studies of the calcification of rachitic bone in solutions of constant calcium concentration and variable phosphate concentration and pH, calcification occurred at points following the curve of the ion product of $(\text{Ca}^{++})^3 \times (\text{PO}_4^{=})^2$ on the acid side of pH 7.3, and following the curve of the ion product $(\text{Ca}^{++}) \times (\text{PHO}_4=)$ on the alkaline side of pH 7.3.⁷³ Against the biologic importance of such a reasonable early precipitate as CaHPO_4 , however, is the occurrence of calcification in individuals with blood calcium and phosphate levels below this critical K_{sp} .¹¹

To obviate difficulties encountered in the precipitation hypothesis, the concept of a catalyzed crystallization of bone salt has been advanced.⁷³ Catalysis is accomplished thus by a special surface of template which serves as a center or "seed" for crystallization. It has been postulated that the tissue or template absorbs calcium ions, which then attract and combine with phosphate ions, or conversely, that the first combination is with phosphate ions. There is insufficient evidence in favor of either theory.⁷³

3. *Bone matrix.*—Recent investigations of bone matrix are particularly germane in view of conventional concepts of osteoporosis. Studies on the relationship of the state of the matrix to calcifiability have suggested that calcifiability is directly dependent upon the state of polymerization or depolymerization of the mucopolysaccharides of the matrix.⁷³ Increased basophilia and metachromasia of the matrix surrounding cartilage cells have been correlated with calcifiability;⁹² in membranous bone formation²⁰ the situation is analogous. Of further interest, similar metachromatic staining of matrix has been noted in calcinosis universalis, calcified pericarditis, calcified bursitis, and renal stones of the calcium phosphate and carbonate types.⁹²

4. *Enzyme studies.*—With the vital importance of enzyme activity in a variety of metabolic processes well established, it is logical to relate enzyme

activity to the staining reactions and calcifiability of bone matrix.

Calcium salts deposit *in vitro* following the destruction of local enzymes only when unphysiologic concentrations are attained.⁴⁴ In the test tube (with the "local mechanism" absent) phosphate added to serum does not form bone mineral, but rather, when a critical ion product is exceeded, a colloidal form of calcium phosphate appears.⁷³

The association of alkaline phosphatase with osteoblastic activity suggested that this enzyme plays a role in calcification. Robison⁹⁰ originally thought that phosphatase cleaves an organic phosphate bond, thereby elevating local phosphate concentration and causing a crucial ion product to be exceeded. However, the optimal pH for this enzyme is high (9.4), the concentration of suitable substrates in the body fluids low, and other non-calcifying tissues are rich in an identical or similar enzyme. Furthermore, although phosphatase activity is associated with the hypertrophic stage of cartilaginous proliferation, it is not found in bone matrix, either calcified or uncalcified.⁷³ And since either iodoacetate or fluoride in concentrations too low to inhibit alkaline phosphatase activity can inhibit calcification of cartilage, a "second mechanism" had to be postulated.⁹¹

Histochemical techniques demonstrate an intimate relationship in distribution between alkaline phosphatase and mucopolysaccharide. This suggests that enzyme plays a part in the formation of the ground substance, perhaps conferring the property of calcifiability upon the matrix. Once the matrix is calcifiable, phosphatase activity is no longer essential for the calcification process.^{43,72} Direct evidence on this hypothesis is not yet available.⁷³

The role of other enzymes in the calcification process has been scrutinized following the demonstration that glycogenolysis is prerequisite to the calcification of cartilage.^{44,45} In healing rachitic cartilage, mineral deposition was noted only in the matrix immediately adjacent to glycogen-containing hypertrophic cells.³⁶ In normal tissue, the glycogen deposits in hypertrophic cartilage cells disappear just prior to or during deposition of bone salt in the cartilage matrix.⁴⁵ Gutman and Yu⁴⁶ have demonstrated that at least the enzyme systems necessary for phosphorylative glycogenolysis play an important role in the mechanism

of endochondral calcification, constituting part of the so-called "local factor." Using phlorizin, iodoacetate, and fluoride to block phosphorylase, 1-3 diphosphoglyceraldehyde dehydrogenase, and enolase respectively, utilization of organic phosphate sources occurring prior to the blocked step in the glycogenolytic pathway was prevented; phosphate sources appearing in the cycle after the block could be utilized.

The steps involved after phosphopyruvate remain obscure. Perhaps a transphosphorylation is involved with transfer of the phosphate of high-energy phosphopyruvate to some unidentified acceptor, which might be the ultimate (still unknown) substance in cartilage matrix undergoing calcification.⁴⁷

Studies on beryllium,⁴⁷ which specifically inhibits alkaline phosphatase, are difficult to interpret because the concentration of beryllium and of various substrates tested are of critical importance. At crucial concentrations, inhibition of calcification occurred when phosphate was supplied as B-glycerophosphate, sodium phenylphosphate, or creatine phosphate. Calcification was not inhibited when inorganic phosphate was supplied; the inhibition of utilization of glucose 1-phosphate, glucose 6-phosphate, and fructose diphosphate could be overcome by raising substrate concentrations. Gutman and Yu⁴⁷ concluded that the enzyme mechanisms involved in the utilization of inorganic phosphate for endochondral calcification differ significantly from those operating in the utilization of B-glycerophosphate and other phosphoric esters which are not in the glycogenolytic series, but which are dephosphorylated by alkaline phosphatase.

The role of enzyme systems in the process of calcification undoubtedly represents a fertile and important area of investigation in this field. Nevertheless, no conclusive evidence has been presented so far that a specific enzyme system is required for the calcification of bony matrix as distinguished from cartilaginous matrix.⁷³ To quote Gutman: "No system of calcification yet proposed takes into sufficient account the important differences disclosed by histological and histochemical study in endochondral calcification, endosteal calcification, and periosteal calcification, nor has any satisfactory mechanism been suggested to explain the complex and diverse actions of the various hormone and vitamins."⁴³

Comments and Discussion

Although the concept of osteoporosis as a deficiency of bone matrix fits the clinical picture of the disorder and its response to hormones which stimulate anabolic processes, it has been difficult to understand the positive calcium balances produced by dietary measures alone. The variability of bone salt composition and the demonstration that the apatite lattice can adsorb or exchange ions from the surrounding medium offer a possible explanation. Although factors influencing calcium absorption are not completely understood, and individual variations are difficult to explain, it seems possible that calcium supplements might increase absorption, produce a transient rise in serum calcium levels, and thereby promote adsorption of additional calcium by bone salt crystals. Increases in bone calcium content too slight to be detected histologically or roentgenologically could perhaps nonetheless cause symptomatic improvement. Thus better-than-adequate mineralization might compensate in part for less-than-adequate matrix. Such a concept could also account for the beneficial effects of strontium therapy.

From their synergistic effect on calcium retention, it is clear that estrogen and androgen possess different mechanisms of action. By analogy with other hormones with known mechanisms of action, it is plausible that gonadal steroids affect the skeleton through acceleration or inhibition of enzymatically controlled reactions. Changes in enzyme concentration occurring in tissues and organs under the influence of hormones can be correlated with changes in their function and with the level of the hormone acting on the end organs. This conclusion is well illustrated by the changes in the alkaline phosphatase, acid phosphatase, adenosine triphosphatase, succinic dehydrogenase, malic dehydrogenase, and total glycolysis of the corpus lutea of the rat during pregnancy and lactation.⁷⁵ No single generalization, however, will serve to describe the changes in enzyme concentration which follow induced hormone deficiencies.⁷⁵

Speculating further, idiopathic osteoporosis and osteogenesis imperfecta may represent a lack of an enzyme concerned in osteogenesis. Absence of such an enzyme might account for failure of hormonal therapy in these cases; yet substrate (? albumin) occurring after the blocked reaction might be utilizable for matrix formation.

For this reason the author finds current research on enzymatic activity in endochondral calcification most challenging. At present the crucial enzymes involved in human endosteal bone formation are not known. Alkaline phosphatase has been related to bone matrix formation and calcifiability only circumstantially. It is hoped that further investigations will disclose the biochemical reaction involved in matrix formation, the enzymes whose presence is required, and the nature of hormonal influences on these enzymes.

Summary and Conclusions

Osteoporosis is a clinical syndrome of bone demineralization, probably resulting from a deficiency of the bone matrix. It is often associated with metabolic disturbances characterized by decreased protein synthesis or increased protein breakdown. In view of present knowledge of hormone and enzyme activity and of recent studies on the enzymology of calcification, it is hoped that further study will demonstrate enzymatic processes involved in bone matrix formation and provide a more rational basis for hormonal therapy.

Therapy, though empirical, is nonetheless often successful. Through mechanisms not entirely clear supplementary calcium, vitamin D, and strontium increase mineral retention and often produce symptomatic improvement. Gonadal steroids also produce calcium retention, probably through stimulation of osteogenesis, and are usually the therapeutic agents of primary importance.

In the relatively few cases where this is possible, the clinician should treat etiologically. In the great majority of cases, he can merely hope to provide the dietary constituents requisite to bone formation and stimulate utilization of these raw materials through intelligent steroid therapy.

As the most common systemic disease of bone, osteoporosis is of major clinical importance in itself. Even more important, investigation of the clinical problems presented has in turn furthered our understanding of hormonal relationships and basic bone metabolism. Recently acquired knowledge of enzymatic activity points the way to future fruitful investigations. It is hoped that knowledge about bone matrix formation gained from studies in relatively uncomplicated osteoporosis may in turn contribute to our understanding of more complex problems in bone disease, such as Paget's disease. One might speculate further that processes crucial to bone matrix metabolism may be

common to other connective tissues, and that the knowledge acquired of osteoporosis may bear clinical fruit in the vast area of the "collagen diseases."

Acknowledgment

The author acknowledges with gratitude the helpful suggestions and criticisms offered by Dr. Simon Koletsky and Dr. Kermit Pines in the preparation of this manuscript.

Current Concepts

Changing Concepts in the Treatment of Tuberculosis

"Plus Ça Change, Plus C'Est La Meme Chose"

R. R. TRAIL, M.D.

London, England

Tuberculosis is a general disease with local manifestations. Recovery depends more on what the patient has in his head than what he has in his lungs.

Sanatorium treatment is essential. It combines necessary bodily rest in open-air conditions, with mental rest away from the worries of home and work.

Graduated exercise to produce auto-inoculation is the only way to prepare for return to life in normal conditions.

The best hope for the patient is to remain under sanatorium conditions in sheltered work.

There is no treatment like artificial pneumothorax, but it should be carried on for the first six months in a sanatorium. Thoracoplasty is a last hope.

It is not necessary to go to a sanatorium for induction of pneumothorax. After a few days in hospital the patient can return to work and continue refills as an outpatient.

Pneumothorax is a long treatment with many possible and dangerous complications. Thoracoplasty is a safer and shorter cure but should be carried out under sanatorium conditions.

Every patient should get back to work as soon as possible.

Sanatorium treatment and collapse therapy are no

longer necessary. Cure can be effected by antibiotics alone which can be given either at home or at a clinic.

Resection is the treatment of choice; it removes the disease entirely and makes rehabilitation unnecessary.

Rest treatment is outdated.

Victory over tuberculosis is in sight.

There are valid doubts whether the disease can ever be banished by specifics even more potent than any now in use.

Resection should not be done until the patient has six months treatment with antibacterials in a sanatorium.

Victory, my foot! Success is not victory, and its criterion in tuberculosis is morbidity not mortality.

Tuberculosis is still a general disease; a clearing x-ray is not the same thing as a cure.

Tuberculosis has become a chronic disease instead of a killing disease. Its modern treatment is creating huge financial problems in after-care that threaten to ruin our medical economy. Every patient should have rehabilitation.

The right treatment is to prevent morbidity by excising primary lung foci and glands, or by giving B.C.G. to all negative reactors.

It is time to get back to treating the patient with disease instead of treating the disease and the bacillus.

THESE statements, which are more or less in chronological order, summarize the experiences with changing concepts of treatment of the chest physician who has been in practice for the past thirty years. Every few years he has seen the emergence of some new panacea, which with time has either lost favor or been modified in its application for various reasons—disappointment with results, advances in surgical technique, war conditions, postwar bed shortage, the changing pathogenesis of the disease, the introduction and general use of antibacterial agents, the increase in the number of the living tuberculous, and continuing morbidity have all played their part.

Throughout the period it is possible to recognize two main trends of treatment: First, a swing away

from treatment directed to the needs of the individual patient, through stages of concentration of his disease, then on his x-ray findings, and latterly on the tubercle bacillus; second, a swing back to the treatment of the individual, led by the psychologist and the neuropsychiatrist, who have been disturbed by the rebellion of the patient against a fixed and impersonal routine. Osler believed the mind even more important than the lung lesion in treatment; today the psychosomatic aspect of pulmonary tuberculosis is being stressed.

Changing concepts are well illustrated in changing attitudes to sanatorium treatment. Reasoning against it over the last ten years may have been practical in the light of postwar difficulties, but it cannot be claimed as being entirely logical. The

after-history results of the 1920's, which appeared within ten years of the general introduction of rest and graduated exercise as the one hope for the tuberculous, were the only results then possible. The sanatorium of those days was trying to make bricks without straw; it consisted of a good middle span of treatment with no supporting ends, since on the one hand some 80 per cent of its admissions were in stages II and III of the disease, and, on the other, it was entirely powerless to implement its advice on the future to those who were fortunate enough to survive to a date of discharge. The recent tirades against it ignore the fact that 90 per cent of stage I cases treated in the 1930's could count on efficient arrest of their disease through the application of graduated rest and the sensible use of medical collapse-therapy. They forget, too, the part it played in the prevention of contact infection, especially in the home; contact infection in industrial life today is a serious problem, to which the loss of residential training is a contributing factor. To cite only the expected failures of the sanatorium savors of opportunism, and of an eagerness to find a new virtue in the necessities of the postwar difficulties of bed-accommodation.

The same illogical reasoning has been apparent in arguments against the use of artificial pneumothorax. Years before it was decried for the incidence of its complications, these had been very materially lessened. X-ray control from the day of induction, and thorascopy where indicated, were generally used. A useless pneumothorax was quickly discarded; for twenty years no physician has talked glibly about "selective collapse." The days of pyo-pneumothorax resultant on cutting adhesions that contained lung tissue are long past. End-results are almost universally excellent where the patient has one physician throughout his treatment and does not receive his refills at any clinic that happens to be convenient, just as if he were merely attending a tire-pumping station.

By 1950 both sanatorium treatment and collapse therapy, medical and surgical, suffered from the dramatic immediate effects of antibiotics and resection, for both were dependent on bed-treatment, and bed-shortage was the outstanding problem. For this shortage some blame must go to ill-conceived propaganda on the dangers of infection used to induce the public to attend mass-radiography centers; it frightened prospective nursing and domestic staff away from employment which

was known to have the lowest incidence of morbidity from phthisis.

Both forms of treatment suffered also from changing ideas on the value of rest treatment. The necessity for wartime production had brought a renewed interest in rehabilitation. In Great Britain grants-in-aid in money and in kind had been made dependent on willingness to get back to some form of work. Although Marcus Paterson's theories on the value of auto-inoculation by graded exercise had been dead for almost twenty years, the ultimate uselessness of a static life was again preached. The new trend was markedly accelerated when pictures appeared in the medical and lay press of patients dancing within a few weeks of starting specific drug therapy. Now that there is no pressure on sanatorium beds many younger physicians are rediscovering the value of rest; there is a return to belief in its benefits during the early stages of antibiotic treatment up to one year, and both before and after the operation of resection.

Knowledge of the changing pathogenesis of phthisis owes much to the increased use of x-ray examination by large and miniature films. Before the outbreak of World War II, however, and therefore before the discovery of streptomycin, there was already evidence of a growing resistance to established disease; and of a growing response to treatment. The death rate was falling steadily, if slowly; by 1948, the prewar position had been recovered in North America and Western Europe. By the mid 1920's, fulminating forms of the disease were disappearing. By the 1930's, complications, such as laryngitis and abdominal disease, were less frequent, and a growing number of patients with cavitation were becoming chronic carriers into old age. On the other hand, the rounded, "Assmann's" focus which became rare in those days is appearing again as the "tuberculoma," which can remain apparently inert for a considerable period under antibacterial treatment and yet produce fresh foci in the lung fields, and x-ray examination of the supposedly healthy discloses hitherto unrecognized forms of adolescent primary disease.

Undoubtedly, this changing pathogenesis had played a part in the dramatic effect on the death rate of the general introduction of the new antibacterial agents in 1948; in England and Wales in 1955 deaths totaled 6,492 as against 19,908 in 1949. This result, however, has presented us with new problems. A rapidly falling death rate has

naturally been accompanied by an equivalent rise in the living rate. The number of cases on clinic registers has reached alarming totals. In England and Wales in 1955 the number was 342,866, an increase of 70,826 since 1949.

Not all of these clinic cases will become sputum-negative, and not all who do so will remain permanently negative. That there is a sense of false security by faith in antibiotics is shown in a recent report of the Chief Medical Officer of the Ford Motor Company at Dagenham; of eighty-two men returned from clinics as fit for work, fourteen were found to have positive sputum, and in another series of seventy-eight, many of whom had been removed from the registers as cured, practically 60 per cent were positive to periodic sputum examination. If falling mortality is to mean remaining infectivity in a growing number of workers in open industry, this is a poor present to the community. There must be more rigorous follow-up for several years of all cases who have at any time returned a positive sputum. We may yet have to reopen sanatorium beds for the segregation of carriers.

Unless such stringent measures are employed, our notification rates and tuberculin conversion rates will not fall in proportion with our death rates. So far in the United States the fall in notifications is only some 3 per cent, per year; in England the number notified in 1955 was 38,134, a fall of only some 15 per cent, against the 65 per cent fall in the death rate since 1949. Our infant and childhood rates of infection have been falling since 1938 with the greater use of pasteurized milk, but 25 per cent of our population become tuberculin-positive between the ages of fifteen and twenty, and the forward age-shift of tuberculinization is being reflected in the increasing number of breakdowns in men aged forty-five to fifty.

These facts are forcing new concepts of treatment aimed at the prevention of morbidity. The recent Medical Research Council trial of B.C.G. and vole-bacillus vaccines in negative-reactors between the ages of twelve and fifteen resulted in the claim that they can reduce morbidity in early adolescence by some 4 per cent. Some surgeons are now advocating resection of tuberculous hilar glands and primary lung foci, and some physicians are asking just how minimal tuberculosis

of the lung has to be before one would not treat it by chemotherapy.

Among the increasing number of survivors, there is an increasing number of disabled. The latest returns of registered disabled in Britain show that the percentage of those disabled by phthisis is exceeded only by that of persons disabled by limb injuries. About one fifth of them are seriously disabled and wholly dependent on state grants. Where antibacterial treatment has made a chronic illness of a killing disease, it is ultimately a failure; the true end of treatment is to return the patient to work in the community of his fellows. Unless rehabilitation and vocational training are recognized as part of treatment and not merely placebos of post-treatment, we shall place an ever-growing load on the State, which will get no return in services at economic ages.

The latest concept of treatment is the psychosomatic. Neuropsychiatrists maintain that as recognized precipitating causes of morbidity in malnutrition and bad hygiene disappear with social services new factors are coming more into evidence in personal reactions to the stress and strain of modern life. This is really a complete turn of the wheel of concepts, not the new speciality some writers would claim it to be. It is none other than the concept expressed forty years ago by Osler as an essential for the physician who would treat his patient as a whole, again forced into the forefront because the individual resents treatment by rule of thumb, however sound this rule may be in its scientific basis.

The lesson of thirty years of the experience of concepts of treatment is evident. Medicine is not, and is never likely to be, based on exact science; it remains an art, because the personal side of the patient has changed little during the five thousand years of medical practice. This art requires experience, difficult to acquire by didactic teaching, and gained only by the sympathetic study of the total family, social, spiritual and medical background of the man who is ill. In its application all concepts of treatment are combined into one treatment; preventive measures, rest, collapse therapy, resection, antibacterials, and industrial and psychologic rehabilitation each take their proper place, because the aim is to deal with the individual requirements of the individual patient.

Continuation Study

A New Technique for the Diagnosis of Intestinal Obstruction

JOHN F. PERRY, JR., M.D., and
STANLEY L. VON DRASHEK, M.D.

Minneapolis, Minnesota

SIMPLE intestinal obstructions can be managed today with a reasonable mortality rate. However, strangulating lesions of the bowel causing obstruction are still formidable clinical problems because of the difficulties in diagnosis and the lethal character of such obstructions if not recognized and treated promptly by operation. An analysis of the experience of the University of Minnesota Hospitals has shown that the mortality rates accompanying strangulation obstruction are three to four times as great as those with simple obstruction. Neither clinical nor radiographic findings are uniformly positive in strangulation obstructions.

Laboratory experience has shown the edematous or hemorrhagic loops of experimental strangulating obstruction which are venous or predominantly venous in character can be readily visualized by x-ray after induced pneumoperitoneum. Such obstructing lesions could be diagnosed less often by conventional radiographic techniques.

Pneumoperitoneography has now been used in a sufficient number of patients with intestinal obstruction so that we feel it offers a definite aid in recognition of strangulating lesions causing obstruction.

By the use of this method the diagnosis of strangulation obstruction has been made in some patients who presented clinical and radiographic findings of simple obstruction only. In others, suspected of having strangulation obstruction, it has given confirmation of the diagnosis by demonstration of the lesion.

Pneumoperitoneum is induced by passing a short

bevel #15 gauge needle through the abdominal wall in the right lower quadrant or some alternate site on the abdominal wall. As soon as the parietal peritoneum is penetrated, a small bore polyethylene tubing is threaded several centimeters into the peritoneal cavity and the needle withdrawn. Air is introduced manually by a syringe and three way stopcock. About 600 cc. of air usually suffices. After introduction of pneumoperitoneum abdominal x-rays are taken in the supine, Trendelenburg and upright positions. The supine pneumoperitoneogram has usually provided the most information. After x-rays have been made, most of the air can usually be removed by aspiration through the polyethylene tubing if desired and the tubing then removed.

The exact indications for pneumoperitoneography in intestinal obstruction cannot be definitely stated at this time. It has been most useful in patients suspected of having intestinal obstruction whose abdominal x-rays appear gasless or nearly gasless. If conventional abdominal x-rays show a "pseudo tumor" sign or gasless area suspicious of a mass, pneumoperitoneography may confirm the presence of a strangulating lesion. We have used it whenever the diagnosis has been in doubt. It should probably not be utilized, however, in the presence of great distension of many small bowel loops.

The potential dangers from puncture of bowel and other viscera, air embolism, or the introduction of air into the acutely inflamed abdomen are recognized. We believe the advantage gained in the diagnosis of potentially lethal strangulating obstructions outweighs these disadvantages.

Summary of paper presented at the University of Minnesota Continuation Course for Surgeons, Minneapolis, May 25, 1956.

TODAY'S APPROACHING CRISIS

Many of the problems of medical practice today stem from the public's lack of awareness as to what is the purpose of medical practice. There are times when we physicians have to pause for a moment before we are able to answer this question. We tend to take what we do daily for granted, so that it becomes difficult to express specifically in words what actually are our activities. If we cannot clearly analyze our own work, then it becomes impossible to expect a less informed public to be able to do so. It is for this reason that I raise the question, what is medicine? Or specifically, what do we sell to the public? Is it good health? Any physician of experience will deny that good health is our commodity, although we hope this will result from our efforts. Do we sell prescriptions or physical examinations or various diagnostic procedures or operations to the public? The answer is no, although a significant proportion of the nonmedical public might disagree with this.

What, then, is medicine? To me medicine is decision. It is a decision based on experience, judgment and training, and, once arrived at, it is decision that is acted upon. Decision will always be the common denominator for every type of medical practice, and any physician who cannot reach a decision fails in the effective practice of medicine. The only commodity that we have to offer the public is decision.

It would seem that the above premise is self evident. However, my experience makes me believe that this is not so. It is my contention that much of organized medicine's difficulty in public relations stems from the fact that the general public regards the physician as a dealer in "things" rather than "ideas." We may not like this attitude; however, not liking it does not make it less true. The physician of generations ago did not have the antibiotics, antihypertensive drugs, the "tranquilizers," or the modern techniques in the diagnosis and treatment of disease, so that the patient consulted him for his opinion relative to his subject. Today, the well informed modern patient believes that penicillin is good for his

"cold," that rauwolfia will cure his high blood pressure, that Equanil will sooth his nerves, and so he consults his physician with the attitude that the physician is the "middle man" in our present scheme of therapy. This is not only a dangerous state of affairs to organized medicine but more so to the general public.

It is my opinion that this situation results from our failure to carry out our responsibility in the education of the public. This, of course, may be due to our failure to remember our true function. The fault, however, is not ours alone. There are many strong socio-economic forces which are inadvertently and directly educating the public in the opposite direction. One of these forces is represented by our present system of health insurance.

I do not wish to imply that these various forms of health insurance are undesirable. On the contrary, such insurance programs have benefited the public. The insurance designers and planners must be congratulated for bringing these programs to their present state of development. The administrative task in the beginning was most difficult. It is almost impossible to imagine the problems encountered in setting up risk tables without the assistance of previous actuarial experience. It is also recognized that for this reason most of these programs developed their basic concept in and around the tangible aspects of medical practice. The result was a specific alignment of these policies along diagnostic procedures, surgical procedures, and the like. Unfortunately, the insurance plans do not recognize the value that must be placed on the most fundamental feature of the practice of medicine, namely, the ability to make a decision and to carry it out for the benefit of the patient. These plans as a result do not specifically evaluate the time and the energy that is necessary to reach such decisions. It is imperative at this time for the future of medical practice and the well being of the public that this oversight be corrected. It must be emphasized that value be placed on ideas as well as on things. We must insist that these changes be made for without them the true function of the physician will be

forgotten and he will truly become the "middle man in therapy." The insurance plans have played an important role in the education of the public concerning medicine. These plans can be a most potent force to influence the modern practice of medicine. The rapid growth of the voluntary companies as well as the reference to compulsory health insurance in the various political campaigns, as well as the increasing demand for broader and broader coverage in labor contracts, attest to this fact. Since this is true, it would seem only reasonable that we define our function clearly and definitely in our own minds and insist that this function be recognized by all. If we fail in this task, others will define this function for us. If this should happen, both organized medicine and the public which it serves will ultimately suffer.

THE TEACHING OF SCIENCE

An important activity of the Minnesota Science Teachers' Association deserves the attention and support of all physicians in our state. This association has done an outstanding job in improving the teaching of the sciences in Minnesota high schools, and its program for attracting larger numbers of able people to this field appears to be promising.

A committee of the association, the Business, Industry, and Teachers of Science Committee (BITS), is sponsoring a Science Teacher's Conference on Friday, May 3, 1957. In order to make possible maximum attendance at the conference by high school teachers, BITS urges the professions and industry to help by making their members and scientists available as substitute or guest teachers in the various high schools on the day of the conference. Thus, a physician might take over a biology or general science class, and a chemist or engineer a chemistry or physics class, freeing the teacher in each instance so that he might attend the Conference.

High school teachers themselves and members of the BITS Committee will communicate with members of the various professional groups concerning this program. Physicians who wish to volunteer their services for this purpose may do so by writing to the principal of their local high school or to Mr. Martin Thames, Secretary of BITS, Bemidji High School, Bemidji, Minnesota.

The physicians of our state are fully aware of the importance of good teaching of scientific subjects in the secondary schools. We are certain that they will welcome this opportunity to be of service in a small but significant way.

ROBERT B. HOWARD, M.D.

RECEPTIONIST VS. TELEPHONE

Dr. Jones' office was full of fidgety people, all glaring—at each other, somewhat, but mostly at Susie Smith, receptionist, who tried to soothe everyone's impatience with periodic announcements that Dr. Jones had been delayed at the hospital but that he expected to be able to leave for the office very shortly. As if it wasn't bad enough to have to listen to the ululations of the people in front of her, poor Susie had to answer the phone, too, and it would choose this day, of all days, to ring its fool head off.

"If that phone rings once more," she mumbled to herself, "I'll tell the person who's calling to go jump in the lake!"

The phone rang. She curbed her impulse to suggest a dip in the drink, thanks to a friendly little gremlin somewhere in the back of her mind who reminded her that she liked to eat and buy a new hat once in a while, and answered the phone in usual fashion. Well, almost. Ordinarily, Susie put all the honey she could muster into her voice when she answered the phone, but on this occasion it was just too much to be pleasant on top of all that had happened. So she let slip a very abrupt:

"Hello!"

Her tone of voice was so chilly the temperature in the room probably lowered a degree or two. . . .

This little episode ends right here. But it's interesting to imagine the reaction of the person at the other end of the line to Susie's abrupt brush-off-type telephone reply. Had the caller happened to be her employer, she might have been in for a mild reprimand. (Not that Dr. Jones himself doesn't get abrupt on the phone once in a while.) If the caller happened to be someone who really was or imagined that he was seriously ill, an answer like the one Susie gave might have been all that was necessary to touch off a vision in the mind of that person of a mean old doctor telling him that whatever was ailing him was a fatal-type illness and that he could be expected to be patted in the face with a spade before too long.

All of which is a means of saying that being abrupt on the phone is to no one's advantage, no matter how you look at it. Or, to be positive rather than negative, telephone courtesy in the doctor's office is extremely important since a good majority of the people who call are probably somewhat upset, and a nice, sincere, sympathetic-but-not-sickeningly-sweet voice helps take the edge off the patient's anxiety.

For whatever it's worth, then, here are some suggestions for all the Susie Smiths everywhere on using the telephone in the physician's office: Answer promptly, greet the caller pleasantly, identify yourself and your office when you call or answer, give the person who's calling time to say whatever he or she wants to say without interrupting, use a friendly but natural tone of voice, speak distinctly (you can't do this with gum in your mouth, Susie), and try to take a personal interest in the caller's problem. To sum it up: Be as personable on the telephone as you would be face-to-face.

NORTHWESTERN BELL TELEPHONE COMPANY

THE WHITE SLAVES OF NEO-SLAVONIA

The rest of the household had gone up to bed. My host thoughtfully replenished both our glasses and settled himself comfortably.

'I suppose you have heard how we have dealt with our Social Evil in Neo-Slavonia?' he asked with a chuckle, 'What do you think of it?'

I confessed that I knew nothing whatsoever about it.

'What!' he slapped his knee, 'haven't you heard? Oh, I must tell you, then. You'll love this.'

'Every now and then we would have outcries against the prevailing laxity of morals, as I expect you do. Bishops, judges and newspapers suddenly wake up, and there's a to-do, and then it all dies down again. The last time it happened, our Prince suddenly took action.'

He laughed immoderately.

'I really ought not to laugh,' he said apologetically, 'but it really was superb. I ought not to be saying this either: but I just cannot make up my mind whether our sovereign is a knave, a fool or a genius. He certainly has the devil's own luck with his Anglophile projects. As usual, he said, "What would the British do?" and before you could say Johann Nosnibor he had inaugurated a Ministry of Masculine Entertainment,

extracted a weekly contribution from every male between the ages of sixteen and eighty-six, and by the subtlest propaganda persuaded all the geishas to be nationalized. There was supposed to be Free Choice, but every male was put on one Nominal Roll or another to begin with. The geishas were allowed to have up to a thousand—or was it two thousand?—names on their lists at a capitation fee of twenty schillings per annum. A nice, steady, assured income, what? . . . Guess what happened?'

'I really cannot conceive,' I replied, 'I've never heard of anything like it.'

'Well, these poor girls got no rest—apart from the statutory day and a half off each week and a four weeks' leave each year. Otherwise, they were on call twenty-four hours a day. It didn't work out quite so badly as that, of course; but they could never be sure of any leisure. And sooner or later a lot of chaps, who otherwise would never have dreamed of calling upon their services, were saying, "I've been stamping my cards now for months and months without getting anything out of it. What about it?" Perfectly natural: just what one would expect.'

'The next thing was that the General Duties Geishas got a bad name for indifferent service. Poor dears, they simply had no time or energy to give really personal attention.'

'Yes, I can see that,' I said, and quoted sententiously—"That individual attention which is expected from all professional men and women, and which professional men and women take pride in giving." Carlyle, wasn't it?'

'I don't know. At any rate, they couldn't. Nobody can when they are metaphorically rushed off their feet. And then, as I told you, we had this Nationalized Litigation Scheme, and that added to their worries. True, all costs and damages are paid by the State, but the publicity of a court case is bad.'

'But what happened to private practice?' I asked,—'Surely it must have enjoyed a terrific boost—or was it made illegal?'

'Not quite: every possible obstacle was put in its way, however. Oddly enough, it fell off considerably. People said, quite reasonably, that they weren't going to pay twice. No. There was much more cunning moves. A hierarchy was established

Reprinted from *St. Bartholomew's Hospital Journal*, London, England, July, 1956.

within the Service: specialist appointments with shorter hours and higher pay, merit awards—you'd never believe the scramble to get into administrative jobs, the applications to Take Silk, and advertisement of posts and the shortlist parades.

'There is one very happy result: no geisha encourages her daughter to follow in her footsteps. They put them into uniform. Domestic service usually; failing that, Medicine.'

'But did the geishas take this lying down, as it were?' I asked.

'Most of them followed their leaders—who were already in administrative jobs—like so many sheep. Every now and then a few reactionaries hold indignation meetings, but it does them no good. There was one the other day in this very township. They moved a resolution deploring the manner in which their profession has been—I don't know the English equivalent. They use a Neo-Slavonian expression which I fancy has a different meaning with you. They say their profession has been *doctored*.'

'No. We only apply that phrase to neo-Tom Cats.'

PETER QUINCE

THE MINNESOTA HUMAN GENETICS LEAGUE

The Minnesota Human Genetics League held its first annual meeting on November 14, 1945. It is remarkable that there were forty-seven charter members and that, as far as is known, none of them was a holdover from the old Minnesota Eugenics Society. Apparently Dr. Minnich, the president of the new society, was not a member of the old one. Although the Dight Institute and its Advisory Committee helped organize the Minnesota Human Genetics League, the two organizations are legally entirely unrelated. The University of Minnesota had thus fulfilled the fourth and final requirement of the Dight bequest by establishing the League. The University was not obligated to guarantee the survival of the League and it was anticipated that the five officers, who were all University professors, would be replaced as the years passed by persons outside the University. The secretary is the only University of Minnesota staff member among the five officers serving in 1956.

One of the functions of the League is to augment and encourage the activities of the Dight

Institute and to interpret human genetics to the physician and the public. Thus while the two organizations are legally independent their programs are functionally parallel.

In 1946, the League suffered a crisis due to the departure of its secretary, Professor C. P. Oliver. At its third annual meeting in 1947 there were only fifty-six members in good standing. It is the secretary who rounds up the new members and prevents the old ones from falling away, once the organization has been established. In 1947, a new director for the Dight Institute and secretary of the League was found. The new man, Sheldon C. Reed, like his predecessor, could not devote much time to membership recruitment, but gradually the League grew so that there are now about 125 members.

The source of strength who has determined its policy, and has given the League its status, has been the president, Professor Dwight Minnich. He served as president of the League for the first decade of its life and last year resigned the office in accord with his belief that rotation of office has merit in itself. He was succeeded by Dr. John S. Pearson of the Rochester State Hospital who brings many talents to the League.

There can be no doubt that if Dr. Dight could return today he would be elated at the growth, stability and progress made by the League under the guidance of Dr. Minnich. He would realize that his investment had paid high dividends. Indeed, as none of the financial return from the Dight trust is utilized directly by the League, the canny old doctor is coming as close to getting something for nothing as anyone could.

It is, of course, the accomplishments of the League that would intrigue Dr. Dight. They are probably somewhat different from what he might have predicted. At any rate, we are ready to review them at long last.

SHELDON C. REED

LIBRARY FACILITIES AT OUR MEDICAL SCHOOL

The staff, residents, interns, and medical students at the University of Minnesota Medical School all feel a need for a new library near the medical campus. The distance separating the present University library from the medical school

This is the fifth in a series of articles on medical students at the University of Minnesota.

has long been a handicap. In a sense, as new buildings are built for the medical school, and as living units for medical students are moved further from the main campus, this distance is becoming even greater.

Medical students are keenly interested in this problem. They find that they have only an occasional hour off between classes in which to study. The time it takes them to get to and from the main library cuts down their study time so much as to often be prohibitive. A few years ago the Medical Student Committee was able to increase the library privileges of medical students and thus render actual time spent in the library more useful. However, this did not solve the problem.

The Medical Student Committee, therefore, became very interested last year when the Minnesota state legislature considered appropriations for a medical library. In fact, Dr. Dennis Kane, then president of the Committee, met with the legislative committee to plead our cause. That legislature finally appropriated almost half of the requested sum, provided that the Federal Government match this sum, according to a bill being considered in Washington. That same bill, though it did not pass last year, is again being considered this year.

The medical students hope to have a large medical library conveniently close to the medical school. We hope to have a library that is open relatively late in the evening as opposed to the present hours of the main library. It is felt that such a library would also fulfill the need for study space for medical students.

At the present time, the main University library does not meet the needs of students, interns, residents, or staff members of the medical school. Nor do the occasional small departmental libraries in the hospital add much to fulfilling those needs. The fate of a medical library again lies with a group of legislators. We hope that they will realize the need.

RALPH B. SWANSON

LIGHTING THE DOCTOR'S OFFICE

The Doctor's Private Office.—A second area to be considered is the doctor's office or consultation room. Here, the patient and doctor meet—often for the first time. It is important that the lighting

be designed to encourage confidence and peace of mind in the patient and still maintain an atmosphere of professional dignity without becoming "cold" or commercial. General illumination and ample light for the physician's desk are the functional requirements.

A combination of ceiling illumination and portable lamps is a practical solution. The ceiling lighting may be fluorescent, either recessed or surface mounted. Care must be taken to use proper shielding. Plastic or glass panels are favored.

If recessed troffers are used, one should be placed directly over the doctor's desk and another at the other end of the room, providing the area is large enough to require two units. Twelve feet in room length is minimum size.

The same arrangement may be used for surface mounted lighting equipment, but greater care should be exercised in proper shielding to reduce direct brightness from fixtures.

In addition, one or two portable table and floor lamps can do much to soften the general appearance of the office and provide a more comfortable, relaxing atmosphere.

The Examination or Treatment Room.—In the examination or treatment room, atmosphere and aesthetics are secondary. Function is all important. And lighting should be designed accordingly.

Since this is the doctor's "work area," a colorful decor is unnecessary, and walls can be painted white for highest light reflectance. Thus, a somewhat higher light level is provided without increasing wattages.

With the emphasis on efficiency, overall lighting calls for a high level of diffused, "shadowless" illumination which has reduced glare to a minimum. A seventy-five foot candle level is usually adequate.

Fluorescent fixtures, recessed if possible and not more than 6 feet on center, are recommended. A room 12 by 12 feet, for example, would use four troffers, each 4 feet long and containing two 40-watt T/12 fluorescent lamps. The same arrangement could be used for surface-mounted fixtures, but unlike those in the doctor's private office, they should be of the direct lighting type rather than indirect or semi-indirect in character.

In addition, the room will probably be fitted with one or two examination lamps peculiar to the field in which the doctor has specialized. Many also find one incandescent spotlight, ceiling

This is the second of two articles on the subject of office lighting.

mounted on a flexible shaft or stem, most helpful in a variety of ways.

Lamp Colors.—Although subtle to the eye, both fluorescent and incandescent lamps come in colors, and their proper use can accomplish much both psychologically and functionally.

There are seven fluorescent and two incandescent bulb colors from which to choose. Fluorescent lamps come in standard cool white, deluxe cool white, standard warm white, deluxe warm white, white, daylight, and soft white. Incandescent lamps come in white (or the ordinary inside frosted bulb), in pearl pink as in the new Softlight bulbs, and also a new Cool-light which is slightly bluish in character.

These lamp colors give different effects and offer many different uses. For example, in the reception room, the new Softlight bulbs produce a warm, friendly light which contributes to a homelike atmosphere and the comfort of waiting patients. Recommended are 75 to 150 watt sizes or the three-light in equivalent wattages.

In the doctor's office, deluxe warm white fluorescent lamps are recommended for ceiling fixtures. They are richer in the red rays than most fluorescents and thus more flattering to both people and furnishings. Super white incandescent bulbs of the proper size for portable floor and table lamps are easy on the eyes.

For the examination room, cool white fluorescent lamps are most efficient. They have no predominating color characteristics and are thus ideal for examination and treatment work. In addition, they make white things look white and clean. The Cool-light incandescent is best here, too, in portable lamps and "goosenecks."

Conclusion—There are many types of lamps and lighting equipment available today. A little extra time invested by the doctor to determine the proper selection and use of each type for his office can pay big dividends in his own "eye comfort" and efficiency, as well as in creating an environment conducive to a growing practice.

D. P. CAVERLY

Lighting Engineer

THE IMPLICATIONS OF THE RHEUMATIC FEVER SURVEY

Prompted by a growing feeling among physicians and public alike that rheumatic fever is declining in frequency and consequently of decreasing importance has a public health problem,

a survey designed to evaluate the frequency of this disease in Minnesota was conducted under the auspices of the Minnesota State Medical Association, Minnesota Heart Association and Minnesota Department of Health. The results of this survey, essentially the response to a questionnaire sent out to all physicians in the state, was reported in MINNESOTA MEDICINE in April, 1956.¹

Surprising to most were the results obtained. On face value they appeared to indicate that rheumatic fever continues to be a problem of considerable magnitude in our state. For example, the 50.8 per cent of state physicians responding to the survey reported having diagnosed and treated 2,297 cases of rheumatic fever in 1955. Extrapolation permitted the survey committee to conclude that Minnesota physicians had probably diagnosed and treated more than 4,000 cases of rheumatic fever during the single year (1955) covered by the survey.

Because of the large number of cases of rheumatic fever reported in the survey in contrast to the small number formally reported to the State Department of Health, two questions of prime importance were raised by the Rheumatic Fever Survey Committee. These were "how many actual cases of rheumatic fever were represented among the 2,297 cases reported by the physicians and "how many the cases reported met the criteria of Jones^{2,3} for diagnosis of this disease." To answer these questions a careful re-evaluation of the reports of a sample group of physicians submitted in the original survey was carried out. As a result of this study⁴ it was found that there was, at most, 20 per cent "over-reporting," and that 90 per cent of the "actual" cases reported met completely the modified criteria of Jones³ for the diagnosis of rheumatic fever.

Conclusions from these two studies now seem inescapable. During the year covered by the survey at least 3,000 acceptably diagnosed cases of rheumatic fever were treated by physicians in the State of Minnesota. Two-thirds occurred in children and no area of the state was exempt. Certainly, rheumatic fever continues to be a clinical and public health problem of real magnitude in our state.

Another aspect brought into focus by the survey deserves special comment. Although appreciable numbers of rheumatic patients were diagnosed and treated by specialists, the great majority were discovered and treated in their home

community by general practitioners—the family physicians. Perhaps with increasing awareness of diagnostic criteria and improved methods of treatment and prophylaxis the site of diagnosis and management of rheumatic patients has shifted from the large medical center and clinic back to the family physician. Such a shift would account, at least in part, for the conviction in many quarters that this disease is disappearing and no longer of practical importance.

Newer methods of prevention of rheumatic fever make imperative a full awareness of the prevailing medical problem represented by this disease and in this wise the survey fills a gap in our medical knowledge.

Although treatment of rheumatic fever remains empirical and to some extent inadequate, every physician has at his disposal extraordinarily effective means for prevention of initial attacks and prophylaxis of recurrences and infectious complications of this disease. In a recently revised statement,⁵ the American Heart Association has presented recommendations of methods for prevention of initial attacks of rheumatic fever by treatment of infections due to the Group A streptococcus, prevention of recurrences by continuous prophylaxis against streptococcal infection and effective prophylaxis against complicating subacute bacterial endocarditis.

Viewed in the light of studies by Rammelkamp et al^{6,7} the results of the rheumatic fever survey suggests that at least 100,000 streptococcal throat infections occurred in Minnesota during 1955 which either were not treated at all or were treated with antibiotics or dosages of antibiotics insufficient to eliminate the Group A streptococcus from the tissues.*

Not every streptococcal infection will be presented to a physician for treatment and, consequently, we cannot expect to eliminate rheumatic fever completely by application of available knowledge concerning its streptococcal etiology. However, much progress will be made in decreasing the incidence of this life-threatening disease, if every physician concentrates his attention on *specific* diagnosis and *complete* treatment of recognized streptococcal infection and utilizes fully available knowledge concerning specific prophylaxis

*Treatment of streptococcal sore throat or scarlet fever with the sulfa drugs will not prevent their non-suppurative sequelae, rheumatic fever and acute nephritis, since sulfa therapy does not eliminate the streptococci from the tissues of the host.

against the occurrence of streptococcal infection in known rheumatic subjects.

The observations of the survey indicating that rheumatic fever is still a common disease might also be interpreted as strong support for a continued program of research directed toward gaining more complete understanding of pathogenic mechanisms involved in this disease and toward developing better methods for its specific diagnosis and treatment.

CHANGING CONCEPTS IN THE TREATMENT OF TUBERCULOSIS

Organization of the Vocational Training Units at Papworth and Enham-Alamein

As the main object of vocational training is job placement, this is kept in view from the date of application for admission. The physician who recommends admission is advised to have his patient seen by his local Disablement Resettlement Officer. This official will know the possibilities of placement in a trade within the scope of our workshops, where we have leatherwork in travel goods, carpentry up to high-class furniture making, carbody building with its associated electrical fitting, metalworking and welding, upholstery, light engineering with tool-making, and printing and book-binding. There are also some vacancies in the

This is the tenth in a series of editorials on pulmonary diseases.

secretarial, draughtsmanship and accountancy sections. After full clinical examination, the patient is seen by the social worker, who will learn the background and economy of his work and his home conditions. Within three to four weeks he can be referred to the training officer and the works manager, and shown round the shops.

Immediately he starts work at three hours per day he draws generous money grants regulated according to his marital state and home commitments. He then progresses by trial and error; we do not attempt to rush the process. First, he attends a preliminary training school for three months to learn by theory and practice the tools and materials of his chosen trade. It would be useless to confine his work to machines for mass production, for it is possible he may have to earn his living in a small business, perhaps on his own.

At the end of the three months a complete review is carried out by a personnel panel, which consists of the medical director, (chairman), the rehabilitation medical officer, the director of industries, the works manager, the social worker and the head nurse. Each reports his own observations, so that a decision can be made on further hours of work in the main shops, and, if necessary, on a change in training if this had not already been decided at the patient's own request. Similar reviews are carried on at three-monthly intervals. Hours of work may be extended or reduced.

If any man is found unsuitable because he is not taking proper advantage of his opportunities, or is not conforming with the disciplines of treatment, he is reported by the personnel panel to a case conference at which representatives of the Ministry of Labour are present. This body has the power to terminate training, but on the other hand it can continue training beyond the statutory limits where medical opinion recommends this course. This latter decision is often recommended for patient-workers who need further active therapy, and are generally in the category likely to go on to settlement in the hostels or in the village housing estates.

The case conference also reviews the reports of the individual works managers and the training officer, and sees to it that training is progressive on bench work. It is therefore in a position to sum up the competence of the trainee for the work arranged for him in his own area by his local resettlement officer, who gets three

months' notice of impending discharge. Every man who completes training can therefore get a certificate, which entitles him on return home to the benefits granted by arrangements made between the trade unions, the Ministry of Labour and the industrial management of the settlements.

On the whole the organization works smoothly. Self-discharges do occur, but in the majority of cases they are due to domestic difficulties. We do not deny that there are difficulties; we do our best to meet them and overcome them, keeping in mind the ever-new aphorism of medical teaching: "remember it is the patient who is ill."

RICHARD R. TRAIL, M.D.
London, England

A new disease of the nervous system, described by pediatricians connected with the New York University-Bellevue Medical Center, was reported to the Practitioner's Society by Dr. L. Emmett Holt, Jr., professor and chairman of the department of pediatrics in that institution.

The disease develops in young infants who appear normal at birth but who deteriorate mentally in the course of a few weeks or months and terminate fatally. The disease runs in certain families. A most characteristic feature of the disease is a strong odor resembling that of maple sugar found in the urine. Although the disease has been called "maple sugar urine" disease, the abnormal substance in the urine is not maple sugar.

The first case was described in Boston about a year ago by Dr. John Menkes, now a member of the pediatric staff of Bellevue Hospital. Recently, a former member of the Bellevue pediatric staff, Dr. Sheldon Miller, now a resident pediatrician at the Meadowbrook Hospital, identified such a case. Studies of this patient's blood and urine carried out in the laboratories of the department of pediatrics by Dr. Roland G. Westall and Dr. Joseph Dancis have gone far to explain the nature of the disease and have indicated the possibility that it may be controlled by diet. This disease is due to an abnormality of the metabolism of three important amino acids—leucine, isoleucine and valine. These amino acids which are among the human dietary essentials, are not handled normally; they accumulate in the blood and affect the composition of the urine. Although the nature of the metabolic disturbance was not identified in time to save the present patient, it is now felt that other patients so affected could be saved by adjusting the amino acid composition of the diet.

World peace cannot be attained until we build peace into the hearts and minds of men. Since physicians are the most intimately acquainted with the physical and mental needs of their patients, they are the most logical engineers for this great moral construction project. If we, more than a half million physicians, assume this task on an individual, personal basis, we may yet succeed where soldiers, statesmen and politicians have previously failed.—GUNNAR GUNDERSEN, M.D., *World Med. J.*, May, 1956.

President's Letter

THE ROLE OF THE BLUE SHIELD IN MEDICINE

Scientific medicine has made advances in the health care of the people far beyond the most ambitious notions of physicians fifty years ago. Members of the medical profession have not only realized great scientific attainments but have made a tremendous contribution to progress in the economic phase of medicine in recent years.

Even though the history of the Blue Shield commences as recently as 1939, with the inception of plans for prepaid medical care through this medium in California, Michigan and New York, the medical profession has successfully developed a method of meeting the costs of medical care in such a way that the prospect of governmentally controlled medicine has receded.

The origin, growth and economic relationship of Blue Shield to the profession are of vital importance to every physician. During the 1930's, the trend toward compulsory governmental health insurance was increasing. It seemed, then, that some positive action by the medical profession was imperative. Since then, the Blue Shield program of voluntary, nonprofit prepaid medical care has become so widely favored and successful that plans of this nature are now found in all but five states, and more than 37,000,000 people have Blue Shield medical-care coverage.

Moreover, the progress that has been made in expanding the coverage provided by Blue Shield has been remarkable. Some Blue Shield plans are now including benefits for in-hospital medical care, anesthesia service, diagnostic laboratory and other services of physicians. Twenty Blue Shield plans now offer contracts to include catastrophic illness or extended benefits applying to such illness.

As striking as these prepaid medical-service plans have been all over the country, no less striking has been the progress made by the Minnesota Blue Shield plan. This plan was organized no longer ago than November of 1947, but it now has an enrollment of more than 800,000, or one of every four persons in Minnesota. It ranks among the first twelve Blue Shield plans of the country in enrollment. Its benefits have been increased repeatedly, and the scope of coverage has been expanded under two contracts which provide benefits for those of low or modest incomes.

At present, the governing body of the Minnesota Blue Shield is a board of directors which consists of eleven members, *all* of whom are physicians. By-laws require that the corporate members elect a board of directors composed of eleven physicians, and that the board of directors consist of one doctor of medicine from each of the nine councilor districts and two from the state at large. The two from the state at large have always been from Minneapolis and St. Paul.

An increase in the size of the corporate body which elects this board of directors has been advocated by some physicians and is under consideration at the present time by the board of directors.

The thought behind the proposal is concerned mainly with a broadening of the base on which the board is elected, so that physicians generally will have a greater interest in and control of the activities of Blue Shield.

The proposal was made originally in a resolution introduced by the St. Louis County Medical Society and it was adopted as the policy of the House of Delegates of the Association at its annual meeting in May, 1956. Whether this proposal, if adopted by Blue Shield in accordance with the action taken by the House of Delegates, would in fact result in any change in the board of directors is conjectural.

The thought has been expressed that broadening of the base would tend to make the members of the medical profession feel more closely associated with the board of directors of the Blue Shield. It seems to me that any procedure which might accomplish this endeavor would be worthy of consideration by everyone.

PRESIDENT'S LETTER

Members of the present board of directors are Dr. R. R. Cranmer, of Minneapolis, president; Dr. O. I. Solberg, of St. Paul, vice president; Dr. C. A. McKinlay, of Minneapolis, secretary; Dr. E. Covell Bayley, of Lake City, treasurer; Dr. C. M. Bagley, of Duluth; Dr. E. M. Hammes, of St. Paul; Dr. P. G. Hoeper, of Mankato; Dr. C. W. Moberg, of Detroit Lakes; Dr. Edwin J. Simons, of Edina; Dr. L. L. Sogge, of Windom; and Dr. W. W. Yaeger, of Marshall.

Dr. Edwin J. Simons, as you all know, is the executive and medical director, and no more devoted and dedicated physician to the cause of the Blue Shield will ever be found.

Mr. F. Manley Brist, of St. Paul, is the legal counsel of Blue Shield, and he has done a superb job in giving legal advice to the board of directors as that body developed Blue Shield to its present highly respected stature.

Members of the board of directors have given unstintingly of their time, knowledge and experience to the service of Blue Shield. Meetings of the board of directors or its executive committee are held at least monthly, and at times more often. It is obvious that much time is required to become acquainted with the many phases of Blue Shield, the contract benefits, the enrollment procedures, fair and reasonable rates for subscribers, the absolute necessity for operation without deficit, the meeting of reserve levels that are recommended by actuaries, and all the other major responsibilities of the physicians who serve on the board of directors. To have these manifold things well done from a policy-making level requires a board of directors with devotion to the cause, sincerity of purpose, willingness to expend much time, and no small degree of experience and judgment. All these are given by members of the board without compensation or request for remuneration.

Because of the efforts of this devoted board, remarkable progress has been made in the development of Blue Shield. Probably no one realizes more fully than this board that there are still many ways in which the coverage of Blue Shield contracts can be improved.

I have known physicians from many places, in this country and abroad. They are a group of human beings who are dedicated to their work. I am sure that no matter who the elected board of directors may be, those who succeed earlier members will continue to show this devotion to the cause, even though it may require much time and experience for them to become as valuable as those who have now served so long and so faithfully.

The Honorable Marion B. Folsom, Secretary of Health, Education, and Welfare, has suggested several ways of "expanding and improving voluntary health insurance to help meet the everchanging needs and desires of the people." This includes coverage to meet catastrophic illness, coverage of older persons, and better coverage of persons who are not members of organized groups and those with low incomes. In trying to stem the tide of some form of governmentally controlled care and in pioneering efforts toward the goals outlined, Blue Shield has demonstrated the ability and willingness of the medical profession to maintain equitably and reasonably the economy of medical practice.

With a united profession, loyal to its own economic progeny, which is Blue Shield, there can be little question that the medical profession will continue to maintain an adequate, effective and proper voice in the economy of medical practice.

A large, elegant handwritten signature in dark ink, reading "J. M. Bergen". The signature is written in a cursive style with a large, sweeping loop at the beginning and end.

President, Minnesota State Medical Association

Medical Economics

Edited by the
Committee on Medical Economics,
Minnesota State Medical Association
George Earl, M.D., Chairman

CAPITOL ACTION SLOW ON HEALTH BILLS

In mid-February there were still no signs of early action on any of the major health bills introduced in Congress to date. The two principal committees on health legislation (Senate Labor and House Commerce) were still unorganized. The House Appropriations sub-committee on health has been organized, however, and is a five-man group instead of a seven. Its chairman again is Representative Fogarty (D., R. I.). Others are Representatives Lanham (D., Ga.), Denton (D., Ind.), Taber (R., N. Y.), and Laird (R., Wis.), the only new member of the group.

New Health Bills Introduced

Bills continue to be introduced. Medical and other problems of the aged continue to carry a priority of interest as do bills on drugs and drug control.

In the military field, a bill has been introduced to assist in the procurement of physicians and other technically and scientifically trained personnel for the military services. Under the provisions of this bill, scholarships would be authorized to cover living expenses, tuition, library and laboratory fees, books and materials.

Bills designed to broaden veterans' benefits also continue to occupy the attention of many members of Congress.

The most important bill thus far concerning federal employe health insurance has been introduced by Representative Lesinski (D., Mich.). It is sponsored by a federal employes' union and provides that the U. S. would pay 50 per cent of the cost of basic or catastrophic health insurance for civilian employes and their spouses and children under 19 years; there would be payroll deductions for the employe's share of premiums. An administration bill is expected to be introduced later.

National Health Insurance Again Proposed

One of the original sponsors of the 14-year-old national health insurance proposal and the son of another co-sponsor have introduced identical

bills on the subject in the House and Senate. The measures are S.844 by Senator Murray (D., Mont.) and H.R. 3764 by Representative Dingell (D., Mich.). Dingell, long-time champion of national health insurance, has won a seat on the committee to which most health legislation will be referred—Interstate and Foreign Commerce.

The bills introduced differ from the original Murray-Wagner-Dingell bill only in their scope. Because some sections have since been enacted into law piecemeal, the 1957 version is minus these features: education of health personnel, medical research, Hill-Burton expansion, aid to rural and shortage areas, more state grants for health work, and grants for maternal and child health.

The bill does provide a contributory system of health insurance covering the working population, similar to social security. A separate bill to be introduced later would charge workers 1½ per cent of earnings or up to \$90 a year, with employers contributing an equal amount. The money would go into the U. S. Treasury under a Personal Health Services Account separate from social security but with the Social Security Administration running the program. Covered workers and their families would be eligible for preventive and diagnostic exams, lab and x-ray services, hospitalization up to 60 days, dental services, more expensive drugs, special appliances and eye-glasses.

BILLS INTRODUCED ON TAX DEFERMENT FOR SELF-EMPLOYED

Representative Jenkins (R., Ohio) and Representative Keogh (D., N. Y.) introduced their bills to encourage the establishment of voluntary pension plans by self-employed individuals in January. These proposals are somewhat similar to the Jenkins-Keogh bills of the last Congress but with lower dollar limits. Unlike the earlier Jenkins-Keogh bills, they extend tax deferment to self-employed persons only. They would permit a self-employed individual taxpayer to deduct from adjusted gross income a limited amount equal to payments made by him each year to obtain retirement income for himself or payments to his beneficiaries or his estate.

WAR SERVICE BRINGS SOME M.D.'s INTO SOCIAL SECURITY

Physicians who served in World War II are covered by social security. Any person who served in the uniformed services from Sept. 16, 1940, until the last day of this year would be treated as though he had earned \$160 per month in wages and as though he had been making contributions to the Social Security Trust Fund.

HOW TO WRITE MINNESOTA CONGRESSMEN

Physicians wishing to contact the Minnesota Congressional delegations should make note of their proper addresses and the names of the members' chief assistants:

Senate

1. Senator Edward J. Thye: 458 Senate Office Building; Home, Sheraton-Park Hotel, Washington. Administrative assistant, Robert Forsythe.
2. Senator Hubert H. Humphrey: Office, 140 Senate Office Building; Home, 3216 Coquelin Terrace, Rock Creek Knoll, Chevy Chase, Md. Administrative assistant, Herbert Waters.

House

First District: Representative August Andresen; Office, 1533 House Office Building; Home, Mayflower Hotel, Washington. Secretary, Reynold Bergquist.

Second District: Representative Joseph O'Hara; Office, 1534 House Office Building; Home, 2813 31st St. N.W., Washington. Secretary, Josephine Peters.

Third District: Representative Roy Wier; Office, 424 House Office Bldg.; Home, Congressional Hotel, Washington. Secretary, Charles Munn.

Fourth District: Representative Eugene McCarthy; Office, 102 House Office Building; Home, 2016 Courtland Place, Washington. Secretary, Clinton R. Boo, Jr.

Fifth District: Representative Walter Judd; Office, 1225 House Office Building; Home, 3083 Ordway St., Washington. Secretary, Verne Johnson.

Sixth District: Representative Fred Marshall; 1207 House Office Building; Home, 904 Chalfonte Drive, Alexandria, Va. Secretaries, Paul Pressler and Gerald Ellert.

Seventh District: Representative H. Carl Andersen; Office, 1314 House Office Building;

Home, 4000 Massachusetts Ave., Washington. Secretary, Susanna Johnson.

Eighth District: Representative John A. Blatnik; Office, House Office Building; Home, 1808 N. Quinn St., Arlington, Va. Secretary, L. J. Andolsek.

Ninth District: Representative Coya Knutson; Office, House Office Bldg.; Home, Continental Hotel, Washington. Secretary, Bill Kjeldahl.

RULES ON OSTEOPATH COMMISSIONING OUTLINED

The defense department has issued a directive outlining policy in the commissioning of osteopaths in the military services, a law passed by the 84th Congress. An osteopath must meet the following requirements, among others:

1. Be a graduate of a college of osteopathy whose graduates are eligible for licensure to practice medicine or surgery in a majority of the states, and be licensed to practice medicine, surgery or osteopathy in one of the states, territories or the District of Columbia.

2. Possess such qualifications as the Secretary concerned may prescribe for his service after considering the recommendations for such appointment by the surgeon general of the Army, Air Force or Navy.

3. Have completed a minimum of three years college work prior to the entrance into a college of osteopathy, plus a four-year course with degree of doctor of osteopathy in a school approved by the American Osteopathic Association, and a year internship or residency training approved by the AOA.

MEDICARE PROGRAM RUNNING SMOOTHLY

In the first eight weeks of the Medicare program, medical treatment and hospital bills totaling nearly \$84,000 were approved for payment by the central office in Washington. Broken down, it came to 623 hospital claims for \$50,083 and 437 medical and surgical care cases for \$33,682.60. Since physicians' billings in this time period were from 11 states and Hawaii and the hospital care obligations were only those handled by Blue Cross, since invoices were not yet submitted by Mutual of Omaha to cover payments made in states where that insurance firm is fiscal agent (as is the case in Minnesota), it is apparent that military

dependents are utilizing these newly-authorized civilian services in large measure. Taking one state's claims at random (Mississippi), Medicare officials were elated to find that 20 per cent of its claims fell below fee schedule maximums. There were eight procedures (out of a total of thirty-nine) in this category: four in obstetrics, two tonsillectomies and two medical cases.

PRESIDENT'S BUDGET REQUEST FOR HEW TOPS \$3 BILLION

More than \$3 billion has been requested by President Eisenhower for Department of Health, Education and Welfare activities in fiscal 1958. The budget includes \$477,545,000 to cover the first year cost of new legislation, mainly dealing with school construction, recommended by the President.

For fiscal 1957 the President had requested \$130 million in Hill-Burton funds (Congress appropriated \$125 million). For fiscal 1958, President Eisenhower has asked Congress for \$121.2 million in Hill-Burton appropriation.

The Public Health Service has requested the following appropriations for fiscal 1958:

Chronic disease and health of the aged, \$2.7 million; Construction grants for medical facilities (both research and training facilities), \$45 million; grants for health services training, \$15 million; nurse training, \$3 million; national health survey, \$1.3 million; Indian health activities, \$50 million, medical research, \$190.2 million. \$1,450,000 has been requested for the operation of the National Library of Medicine.

The budget sought for the Food and Drug Administration was set at \$10,554,500. The Social Security Administration budget request was for \$1,733,165,000.

Attacks against medical items in the Federal budget indicates a bi-partisan campaign in the Senate for ever higher health appropriations. Senator Margaret Chase Smith (R., Maine) and Senator Lister Hill (D., Ala.) charged the Administration with 1, withholding \$10 million in medical research grants which Congress expected the Public Health Service to allocate this year; 2, employing bookkeeping legerdemain to make it appear that an additional \$7 million will be provided for research aid in 1957-58 when project funds actually will be less because more money will have to be drained off for higher overhead payments; 3, proposing a "quite disappointing"

\$2.7 million in project grants for the aging and chronically ill after having led the nation to believe a more adequate program would be recommended by the White House this year. The statement of the two Senators also deprecated budgetary provision of only \$3 million to inaugurate a new program of construction aid to medical and dental schools. With aggregate needs running into hundreds of millions, that sum "is hardly a drop in the bucket," the Senators asserted.

BRITISH PHYSICIANS QUOTED

Salary Squeeze

British doctors, under the socialized medicine program, have not had a pay raise since 1951. During this period the costs of living in England has increased about 24 per cent. The doctors say their present average pay of \$6,160 is not enough to meet rising living but a ministry of health spokesman is quoted as saying a 24 per cent boost in fees "could not be afforded under the present conditions."

British Journal Editorialized on GP

A recent issue of the *British Medical Journal* says that "The difficulties which beset the general practitioner are in many respects different from those which await the consultant. In the case of the former there is lack of time, the wide field of knowledge to be embraced, and a year-long familiarity with the patient. There are but few occasions on which a general practitioner can devote 20 minutes or more to history-taking, yet most mistakes in diagnosis are due to inadequate anamnesis. In the last few years this obstacle has been increased to an alarming extent by the paramedical duties inflicted on him by the Health Service. To the consultant this difficulty does not exist in private practice. The general practitioner has, furthermore, to exercise reasonable knowledge and skill in medicine, surgery and obstetrics. In thus doing, his overall efficiency is greater than that of the consultant or specialist. It is to be hoped that Her Majesty's judges will not fail to make clear to juries in the litigation which threatens to deter our young men from acceptance of responsibility."

FDA CIRCULARIZES ON HOXSEY CURE

The Food and Drug Administration is mailing out to all postoffices and substations in the U. S., a poster warning the public on the Hoxsey "cancer

ure" FDA officials said they took this unusual step because final court action against the Hoxsey group will not be completed for some time.

HEALTH STATISTICS REVEALED

Mental Hospital Population Decreases

Minnesota's mental hospital population continues to decrease as it has since February, 1956, except for a slight increase in August. During the past year there was a net increase in population in all types of state institutions except for the mentally ill, inebriates and patients at Gillette hospital.

State Ranks High in Health Facilities

A national report on hospital facilities shows that Minnesota is well above the national average in available facilities. Only six states west of the Atlantic seaboard have more general hospital beds per 1,000 of population than Minnesota.

Population Soars in Ten Years

Since 1946 this country has had an explosion of growth. In 1946 the population was 141,389,000; in 1956, 168,091,000—up 19 per cent. There were more babies born (up 23 per cent); fewer dying at birth (down 23 per cent); fewer mothers dying in childbirth (down 75 per cent) and a lower death rate (15 per cent).

In Minnesota last year the number of live births hit a new high of 81,800. Death rates rose one tenth to 9.2. Maternal deaths dropped for a new low of 0.2 per 1,000. Top killer in the state was heart disease, up four per cent to 37.7 per cent of total deaths; cancer was second, constant at 17 per cent while diseases of the liver and gall bladder rose from tenth to ninth place.

ENDOMETRIAL HYPERPLASIA

(Continued from Page 157)

cases of endometrial carcinoma following known hyperplasia will continue.

Summary

1. One hundred and sixty-two patients with proven endometrial hyperplasia who were treated between 1939 and 1949 have been used to study

the problem of the relation between this disease and adenocarcinoma of the endometrium.

2. Treatment consisted of conservative therapy (curettage, progesterone, et cetera in ninety-five, x-ray sterilization in fifty and hysterectomy in seventeen. Of the 162 patients, 139 could be traced. Of these, a further seventeen had been treated by hysterectomy elsewhere.

3. In the thirty-four with surgical specimens and the remainder of those followed, no adenocarcinoma of the endometrium has been found.

4. No evidence has been uncovered to suggest that endometrial hyperplasia or its conservative treatment, as applied here, is cancerigenic. The choice of treatment of endometrial hyperplasia should be determined on other grounds than the fear of the precancerous significance of endometrial hyperplasia.

Minnesota State Medical Association

Revision of Articles of Incorporation, Constitution and By-laws

At the bottom of this page you will find a notice stating that at the next annual meeting of the Minnesota State Medical Association the present Articles of Incorporation, Constitution and By-laws of the Association will be considered for amendment, together with proposed revisions of same as recommended by the Council after exhaustive study and deliberation.

Several developments have necessitated revision of the Articles of Incorporation. First, changes were necessary to meet the requirements set out in the Minnesota Nonprofit Corporation Act, Chapter 550, Laws of Minnesota 1951, relating to organizations such as ours. Our Articles of Incorporation were adopted in the year 1869 and amended in 1937. Secondly, amendments were needed to protect our tax-exempt status with regard to personal property taxes levied by Ramsey County.

This action, of course, affected the Constitution and By-laws under which the Association was operating, and this seemed to be an appropriate time to thoroughly review and revise these instruments in detail. Also, many component county medical societies have indicated a desire and need for revision of their constitution and by-laws. Accordingly, a special committee of the Council and the Council, with the assistance of Mr. Jule Hannaford, legal counsel, developed the proposed new

By-laws for the consideration of the House of Delegates at the meeting in Saint Paul, May 12 and 13. Under the new code, a constitution is no longer required.

We have endeavored to eliminate inconsistencies between our By-laws and those of the American Medical Association, and otherwise modernize and improve our organizational structure.

We would appreciate each member reviewing this material carefully and forwarding constructive criticism or suggestions for the consideration of the Council and the House of Delegates. These suggestions may be sent to the state office, 496 Lowry Medical Arts Building, Saint Paul.

When amendment and adoption of these By-laws is completed, we will undertake to make available some suggestions or models for revision of the constitution and by-laws of component medical societies. Several societies have also indicated that the charter issued to the society has been lost. It may be desirable to consider re-issuance of these charters.

Please give these matters your close personal attention, and we shall appreciate receiving your suggestions.

J. A. BARGEN, M.D., *President*

C. L. OPPEGAARD, M.D., *Chairman
of the Council*

NOTICE OF ANNUAL MEETING

NOTICE IS HEREBY Given that at the annual meeting of the House of Delegates to be held at Saint Paul, Minnesota, on May 12 and 13, 1957, there will be brought up for discussion and adoption the following resolutions:

1. A resolution repealing in their entirety the present Articles of Incorporation, Constitution and By-laws of the Minnesota State Medical Association.
2. A resolution adopting in lieu thereof new Articles of Incorporation and new By-laws in the form attached hereto as Exhibits 1 and 2, respectively.

NOTICE IS FURTHER GIVEN That the Council of the Minnesota State Medical Association at its meeting held in Saint Paul, Minnesota, on February 10, 1957, proposed adoption of such new Articles of Incorporation and new By-laws and directed that the same be submitted to the House of Delegates for adoption.

Dated February 10, 1957

B. B. SOUSTER, M.D.
Secretary

**ARTICLES OF AMENDMENT
TO
ARTICLES OF INCORPORATION
OF
MINNESOTA STATE MEDICAL ASSOCIATION**

BE IT RESOLVED That the Articles of Incorporation of this corporation be and the same hereby are amended in their entirety to read as follows:

ARTICLE I

The name of this corporation shall be Minnesota State Medical Association.

ARTICLE II

The purposes of this corporation shall be community welfare, community health and scientific education, and shall be limited to bringing into one compact organization the entire medical profession of the State of Minnesota and uniting with similar societies of other states to form the American Medical Association; promoting the science and art of medicine; elevating the standard of medical education so that the profession shall become more capable and honorable within itself and more useful to the public in the prevention and cure of disease and adding to the comforts of life; fostering, to that end, the presentation of papers, articles, findings and studies by its component county and district medical societies in the field of medical research, diagnosis, therapy, operative procedure, prevention of disease and promotion of the public health; assisting officials and agencies of the State of Minnesota with advice and service in the administration of its medical, hospital, welfare and public health programs; promoting through its component county and district societies, continuous advice and assistance in county welfare and public health programs; and promoting high standards of medical and health service in all public programs established for the welfare of the people of Minnesota.

ARTICLE III

The corporation does not and shall not afford pecuniary gain, incidentally or otherwise, to its members or to any component county or district medical society and shall not be operated for the purpose of making

any profit. No part of the earnings of the corporation shall enure to the benefit of any member or any component county or district medical society. All income of the corporation shall be used for the fulfillment of the purposes for which it was formed, including operating expenses of the corporation. In the event of a dissolution of the corporation, any and all assets of the corporation shall be distributed or conveyed only to a like corporation or institution or to an academy, college, seminary of learning, university, public hospital, institution of purely public charity or to the State of Minnesota.

ARTICLE IV

The corporation shall have authority to perform all acts necessary and proper to accomplish its purposes as set out above and not repugnant to law and shall have the authority specifically provided by Chapter 317 of Minnesota Statutes 1955 and any acts amendatory thereto.

ARTICLE V

The period of duration of this corporation's existence shall be perpetual.

ARTICLE VI

The location of the registered office of this corporation within the State of Minnesota shall be 496 Lowry Medical Arts Building, Saint Paul, Minnesota.

ARTICLE VII

The members of this corporation shall have no personal liability for the obligations of the corporation.

ARTICLE VIII

This corporation has no capital stock.

ARTICLE IX

The Board of Directors of this corporation shall have authority to amend the Articles of Incorporation of this corporation.

**BY-LAWS OF
MINNESOTA STATE MEDICAL ASSOCIATION**

ARTICLE I

TYPES OF MEMBERSHIP

1.1 Membership in the Association shall be limited to individuals. Membership shall be of three types: active, honorary and affiliate, any one of which may be broken down into different classes.

1.2 Each person by becoming a member of the Association agrees to comply with and be bound by all the provisions of the Articles of Incorporation and By-laws of the Association, as now or hereafter amended, the Constitution and By-laws of the American Medical Association, as now or hereafter amended, and the

Principles of Medical Ethics of the American Medical Association, as now or hereafter amended.

ARTICLE II

COMPONENT SOCIETIES

2.1 The members of the Association shall be organized into county and district medical societies, each of which shall be known as a component society, chartered by the Association, as hereinafter provided. Not more than one component society shall be chartered to operate in any county except in a county so large in area as to make it impractical for one society to operate. A component society may be chartered to

operate as a district society in two or more counties which are sparsely settled. The territorial jurisdiction of each component society shall be set forth in the charter issued to it by the Association.

2.2 Any component society which has adopted principles of organization employing the substance of Articles II and III of the Articles of Incorporation of this Association and not otherwise in conflict with the Articles of Incorporation and By-laws of the Association may, upon approval of its application therefor by the House of Delegates, become a component society and receive a charter evidencing the fact that it is a component society. Each charter so issued shall be signed by the President and the Secretary of the Association.

2.3 Nothing contained in any charter so issued or in the Articles of Incorporation or By-laws of the Association and no action of the House of Delegates or of the Council shall bind or commit any component society to carry out any policy or recommendation of the Association not contained in the Articles of Incorporation or By-laws.

2.4 Any charter issued to a component society may be revoked by the House of Delegates if such component society acts in violation of the Articles of Incorporation or By-laws of the Association.

2.5 A person desiring to become a member of a component society must join the component society having jurisdiction over the area where he resides; provided, however, that where a person maintains his principal office in one county and his residence in another he may join either the component society having jurisdiction over the area where he maintains his principal office or the component society having jurisdiction over the area where he resides; and provided, further, that a person residing on or near a county line may join the component society most convenient for him if he first obtains the consent of the component society having jurisdiction over the area where he resides.

2.6 Each component society shall have general direction of the affairs of the profession in its county or district, and its influence shall be constantly exerted for bettering the scientific, moral, and educational condition of the county or district, and systematic efforts shall be made by each member, and by the society as a whole, to increase the membership until it embraces every qualified physician in the county or district.

2.7 Each component society shall judge the qualifications of its own members, but, as such societies are the only portals to this Association and to the American Medical Association, ample opportunity to become a member shall be given to every physician in the county or district who is eligible according to the provisions of this Constitution and By-laws.

2.8 The Secretary of each component society shall keep a roster of its members and of the non-affiliated registered physicians of the county or district, in which shall be shown the full name, address, college and date

of graduation, date of license to practice in this state and such other information as may be deemed necessary. In keeping such roster the Secretary shall note any change in the personnel of the profession by death or by removal to or from the county or district, and in making his annual report he shall be certain to account for every physician who has lived in the county or district during the year.

2.9 The Secretary of each component society shall forward the dues of its members, together with its roster of officers and members, list of delegates and list of non-affiliated physicians of the county or district, to the Secretary of the Association on or before April first of the year for which they are levied and shall forward the assessments of its members within the time specified therefor.

2.10 Each component society which fails to forward to the Secretary of the Association the dues of its members and said roster on or before April first of the year for which they are levied, shall be held as suspended and none of its members or delegates shall be permitted to participate in any of the business or proceedings of the Association or of the House of Delegates until such requirements have been met.

ARTICLE III

ACTIVE MEMBERS

3.1 A person shall be eligible to become an active member only (a) if he holds the degree of Doctor of Medicine or Bachelor of Medicine issued by an institution of learning accredited by the American Medical Association at the time of conferring such degree, (b) if he is (i) licensed to practice medicine in the State of Minnesota or (ii) licensed to practice medicine in another of the states or the District of Columbia or (iii) not engaged in the active practice of medicine, not licensed so to do, but engaged within the State of Minnesota in an activity allied to medicine which does not require licensure from the State of Minnesota, and (c) if he is a member of a component society.

3.2 Each member of a component society of the Association shall become an active member of the Association upon election thereto by his component society and upon receipt by the Secretary of the Association of the full dues and assessments payable during the then current fiscal year of the Association if such election occurs prior to July 1, or one-half thereof if such election occurs on or after July 1, for the class of active membership to which he was elected.

3.3 Active members shall be divided into the following classes:

A. *Active Member, Regular.* Regular active members shall be those who pay the full dues and assessments of the Association.

B. *Active Member, Life.* A person who shall have been a regular active member of this Association or of another constituent association of the American Medical Association and this Association for forty years and

CONSTITUTION AND BY-LAWS

shall have reached the age of 70 years shall be eligible to become a life active member upon election thereto by the Council.

C. *Active Member, Service.* A regular active member of the Association who is called to temporary duty in the armed forces of the United States shall be eligible to become a service active member on the January 1 or July 1 which next follows the date of his entrance into military service, upon election thereto by the Council and to retain such class of active membership until the January 1 or July 1 which next follows his discharge from the armed forces of the United States.

D. *Active Member, Associate.* A regular active member of the Association who because of disability is unable to engage in the active practice of medicine or who has retired from the active practice of medicine, shall be eligible to become an associate active member upon election thereto by the Council and to retain such class of active membership so long as he does not engage in the active practice of medicine.

E. *Active Member, Residency.* Any person who shall be engaged in a residency program approved by the Council on Medical Education and Hospitals of the American Medical Association, who shall be a residency member of a component society of this Association, and who applies therefor within five years following his graduation from medical school (provided that time spent in the armed forces of the United States shall be excluded in calculating such five year period) shall be eligible to become a residency active member upon election thereto by the Council and to retain such class of active membership until he ceases to be engaged in graduate study or work.

ARTICLE IV

DUES AND ASSESSMENTS OF ACTIVE MEMBERS

4.1 The annual dues and assessments payable by active members of the Association and, in the case of assessments, the time for payment thereof shall be established for each fiscal year of the Association by the Council but only in accordance with recommendations with respect thereto by the House of Delegates.

4.2 Each active member, unless exempted therefrom, shall pay to his component society for transmittal to the Secretary of the Association the annual dues and assessments so established. No applicant for membership in the Association shall become a member until the dues and assessments payable by him for the then current fiscal year of the Association have been received by the Secretary of the Association.

4.3 The following exemptions from the payment of annual dues and assessments with respect to the following types of active members shall apply:

A. *Life Active Members.* No dues or assessments shall be payable by life active members.

B. *Service Active Members.* Service active members shall be excused from the payment of dues and assessments for the period beginning on the January 1 or July 1 following the date of their entrance into military service and shall resume payment of dues and assess-

ments on the January 1 or July 1 following the date of their release from military service.

C. *Associate Active Members.* No dues or assessments shall be payable by associate active members.

D. *Residency Active Members.* Residency active members shall pay dues of \$5.00 per year but shall be exempted from the payment of all assessments.

4.4 Annual dues shall be paid to the Secretary of the component medical society by January 1 of the fiscal year with respect to which they are payable. Assessments shall be paid to the Secretary of the component medical society on the date prescribed in the notice with respect thereto.

4.5 Regular active members and residency active members shall be entitled to receive, upon payment of their dues and assessments for a fiscal year of the Association, a subscription to Minnesota Medicine for such fiscal year. All other classes of active members shall not be entitled to receive a subscription to Minnesota Medicine but may receive the same upon payment of the regular subscription price therefor.

ARTICLE V

HONORARY MEMBERS AND DUES THEREOF

5.1 Any person who holds the degree of Doctor of Medicine or Bachelor of Medicine and who is distinguished for his service or attainments in the field of medicine, public health, research or other scientific work contributing to medicine shall be eligible to become an honorary member of the Association upon recommendation of the Council and election thereto by the House of Delegates.

5.2 Honorary members shall pay no dues or assessments to the Association and shall not have the right to vote or hold office.

ARTICLE VI

AFFILIATE MEMBERS AND DUES THEREOF

6.1 Any person who is distinguished for his services in any field of science allied to medicine or in the field of public health shall be eligible to become an affiliate member of the Association upon recommendation of the Council and election thereto by the House of Delegates.

6.2 Affiliate members shall pay no dues or assessments to the Association and shall not have the right to vote or hold office.

ARTICLE VII

TERMINATION OF MEMBERSHIP

7.1 Any member of any type or class who is not in default in the payment of dues or assessments and against whom no complaint or charge is pending may at any time file his resignation in writing with the Secretary of the Association and he shall cease to be a member of the Association as of the date such resignation was filed.

7.2 Dues of a member shall become delinquent if not received by the Secretary of the Association by

June 1 of the year for which levied and assessments of a member shall become delinquent if not received by the Secretary of the Association by the date specified therefor, and any member whose dues or assessments become delinquent shall be suspended from membership if he fails to pay the same to the Secretary of the Association within thirty (30) days after notice of his delinquency has been sent by registered mail to his address as the same appears on the records of the Association by the Secretary of the Association. Any member who is suspended from membership in the Association by reason of the provisions of this section may not be reinstated into membership in the Association until all dues and assessments with respect to the year in which he was suspended (but not with respect to any subsequent year) and all dues and assessments for the year in which he applies for reinstatement shall have been paid in full.

7.3 Any member who is licensed to practice medicine in the State of Minnesota and whose license so to do is revoked or any member who is convicted of a felony shall, upon the occurrence thereof, forthwith cease to be a member of the Association.

7.4 Any member who ceases to be a member of a component society, whether for non-payment of dues, for suspension, for expulsion or for any other cause whatsoever, shall cease to be a member of the Association for the period of time for which he was suspended or expelled from such component society.

7.5 Any member who has been found by the Judicial Committee to be guilty of misconduct as a physician or in violation of the Articles of Incorporation or By-laws of the Association, the Constitution or By-laws of the American Medical Association, or the Principles of Medical Ethics of the American Medical Association may, after a hearing before such Judicial Committee, as hereinafter provided, be censored, suspended from membership in the Association for such period of time as the Judicial Committee shall deem appropriate, or expelled from membership in the Association.

ARTICLE VIII

DISCIPLINARY ACTION

8.1 There shall be a Judicial Committee consisting of nine members appointed by the Council, none of whom shall be a Councilor and no two of whom shall be members of component societies in the same Councilor District. The term of each member shall be for a period of three years commencing January 1. The terms of the members shall be so arranged that not more than three shall expire each year. No member of the Judicial Committee shall hear or pass upon any matter in which he or any member of his family is personally involved.

8.2 The Judicial Committee shall have authority to hear the appeal of a member from a decision of his component society disciplining him and to affirm, modify or reverse any such decision; provided notice of appeal is filed with the Secretary of the Association

within 6 months of the decision of such component society. Appeals shall be in writing, shall set forth the grounds of the appeal, and shall be signed by the appellant. Appeals shall be limited in scope to question of law and procedure. The findings of a component society as to the facts in any dispute shall be final and shall not be subject to review on appeal.

8.3 The Judicial Committee shall also have authority to conduct hearings to determine whether or not a member of the Association has been guilty of misconduct as a physician or of violation of the Article of Incorporation or By-laws of the Association, the Constitution or By-laws of the American Medical Association, or the Principles of Medical Ethics of the American Medical Association and, if the Judicial Committee shall find a member guilty thereof, to take appropriate disciplinary action against such member which may include censorship, suspension from membership in the Association for a specified period of time or expulsion from membership in the Association. No such hearing shall be held unless the accused member shall have been furnished with a written statement of the charges against him and shall have been afforded adequate opportunity to prepare a defense. The Judicial Committee shall have authority to compel any member of the Association to appear at any such hearing and give testimony. At any such hearing the accused member shall be given the opportunity to appear and give such testimony as he may desire, and to be present himself or by counsel while any other person gives testimony and to cross-examine such person. The Judicial Committee shall make its decision promptly after the hearing and shall notify the accused member of its decision in writing.

8.4 Before hearing any appeal from a component society or before commencing any disciplinary action, the Judicial Committee shall make every effort to conciliate and settle the dispute.

8.5 Any decision of the Judicial Committee affirming a decision of a component society which disciplines a member or disciplining a member may be appealed to the appropriate agency of the American Medical Association upon such terms and conditions and in accordance with such procedure as may be set forth in the Constitution and By-laws of the American Medical Association. Any decision of such agency of the American Medical Association shall be final.

ARTICLE IX

VOTING BY MEMBERS

9.1 No member of the Association shall have any right to vote on any matter affecting the Association, except the right to vote for election of members of the House of Delegates, as hereinafter provided.

9.2 The members of each component society shall annually elect from among the members of such component society one Delegate and one Alternate Delegate to the House of Delegates for each 50 active members of such component society and for any fraction thereof

CONSTITUTION AND BY-LAWS

s recorded on the books of the Association on December 31 of the preceding year. A component society which has less than 50 active members shall be entitled to elect one Delegate and one Alternate Delegate. Annually during the month of January the Secretary of the Association shall notify each component society of the number of Delegates and Alternate Delegates which its members are entitled to elect for such year. The term of office of each Delegate and each Alternate Delegate shall commence on such date and continue for such period of time as shall be specified by the component society electing him. Only active members of the Association who are members of a component society shall be entitled to vote for the election of or to hold the office of Delegate or Alternate Delegate.

9.3 Voting shall not be cumulative and shall not be by proxy.

9.4 Any Delegate or Alternate Delegate so elected may be removed from the office to which he was so elected by the vote of a majority of the members of the component society which elected him.

ARTICLE X

MEETINGS

10.1 The annual meeting of the Association shall be held at such time and place as the Council may determine. In fixing the time and place of each annual meeting the Council shall follow any directions with respect thereto adopted by the House of Delegates.

10.2 Special meetings of the Association may be called at any time by the President with the consent of two-thirds of the Councilors or shall be called by the President at the request of twenty Delegates representing at least ten component societies.

10.3 All meetings of the Association shall be open to all members and their guests.

10.4 The annual meeting of the House of Delegates shall be held at the same time and place as the annual meeting of the Association and at such time and place as the Council shall determine.

10.5 Special meetings of the House of Delegates may be called at any time by the Speaker or the Vice-Speaker and shall be called by the President at the request of two-thirds of the Councilors or twenty Delegates representing at least ten component societies.

10.6 Written notice of the time and place of each annual meeting and of the time, place and purposes of each special meeting of the Association and of the House of Delegates shall be given by the Secretary to each Delegate and Alternate Delegate not less than five nor more than thirty days prior to the time fixed therefor.

10.7 An annual meeting of the Council shall be held at the time of the annual meeting of the Association at such time and place as the Council may determine.

Special meetings of the Council may be held at such times as the Council may determine or upon the written request of the Chairman of the Council or of any three Councilors.

10.8 Written notice of the time and place of each annual meeting and of the time, place and purpose of each special meeting of the Council shall be given by the Secretary to each member of the Council not less than five nor more than thirty days prior to the time fixed therefor.

ARTICLE XI

HOUSE OF DELEGATES

11.1 The House of Delegates, consisting of the Delegates elected by the component societies as hereinbefore provided, shall be the governing body of the Association. It shall have authority to recommend to the Council from time to time the dues, assessments and other charges payable by members, but no such dues, assessments or other charges shall be recommended except by the affirmative vote of two-thirds of the entire House of Delegates. It shall have authority to appropriate funds of the Association for such purpose or purposes as it deems appropriate, but no appropriation of funds by the House of Delegates shall become effective until approved by the Council.

11.2 The word "Delegate" as used herein refers to a duly elected Delegate or, in his absence or inability to serve, the Alternate Delegate duly authorized to substitute for such Delegate or, in the absence or inability to serve of all duly elected Delegates and Alternate Delegates representing one component society, an Acting Delegate appointed as hereinafter provided. If there is present at any meeting of the House of Delegates no Delegate and no Alternate Delegate from a component society, the House of Delegates may appoint from among the members of such component society present at such meeting Acting Delegates for such component society who shall serve only during the absence of the Delegates and the Alternate Delegates of such component society.

11.3 The House of Delegates shall meet during the annual meeting and at such time or times as may be necessary to complete its business. It may adopt such rules and procedures for the transaction of its business as it deems suitable and shall be the judge of the election and qualification of its members.

11.4 Thirty or more Delegates representing at least 17 component societies shall constitute a quorum. If, at any meeting of the House of Delegates at which a quorum has been present, one or more Delegates withdraws from the meeting so that a quorum is no longer present, the proceedings shall be suspended until a quorum is again present.

11.5 All meetings of the House of Delegates, except executive sessions, shall be open to all members of the Association. The following persons shall have the privilege of attending all meetings of the House of Delegates, except executive sessions, and shall have the

privilege of the floor but no right to vote: the President, the President-elect, the first Vice-President, the Councilors, the Secretary, the Treasurer, the past Presidents, and the Delegates and Alternate Delegates to the American Medical Association. The Speaker or a majority of the Delegates present shall have authority to declare which sessions of the House of Delegates shall be executive sessions and to invite persons who are not Delegates to be present at executive sessions.

11.6 At each annual meeting the House of Delegates shall elect from among the active members of the Association a Speaker and a Vice-Speaker of the House of Delegates, such officers of the Association as are hereinafter provided for, Councilors to replace those whose terms are expiring, and such Delegates and Alternate Delegates to the American Medical Association as this Association may be entitled to elect under the Constitution and By-laws of the American Medical Association.

11.7 The Speaker and Vice-Speaker of the House of Delegates shall be active members of the Association and may, but need not be, elected from among the Delegates and Alternate Delegates. The Speaker and Vice-Speaker shall each serve for a term of one year beginning on the first of the calendar year following his election and thereafter until his successor is elected and qualified.

11.8 Each Delegate to the House of Delegates shall be entitled to one vote. No Alternate Delegate shall be entitled to any vote except during the absence of the Delegate for which he is an Alternate, in which case he may cast the vote which such Delegate would be entitled to cast were such Delegate present. Voting shall not be cumulative nor by proxy. Neither the Speaker nor the Vice-Speaker shall have any vote except in the case of a tie vote, in which case the Speaker or, in his absence, the Vice-Speaker may cast one vote.

11.9 The Speaker shall be the presiding officer at all meetings of the House of Delegates and shall perform such duties as custom and parliamentary usage require. The Speaker shall have authority to appoint such reference or other committees as he deems necessary to carry out the business of the House of Delegates. Members of all such committees shall be Delegates or Alternate Delegates.

11.10 The Speaker shall, prior to each annual meeting, appoint a Nominating Committee to report to the annual meeting a slate of candidates for the offices of Speaker and Vice-Speaker and for the offices of the Association (exclusive of Councilors and Delegates and Alternate Delegates to the American Medical Association) to be filled at such annual meeting. Such Nominating Committee shall consist of one Delegate or Alternate Delegate from each Councilor District. The Speaker shall designate the Chairman of the Nominating Committee and shall serve as an ex officio member thereof. The Speaker shall obtain from each Councilor

the name of one member from such Councilor's district whom such Councilor believes qualified to serve as first Vice-President and shall submit the list of such name to the Nominating Committee. After the Nominating Committee has made its report to the House of Delegates, any Delegate may nominate any eligible member for any office of the Association to be filled at such annual meeting.

11.11 Either the Speaker or the Vice-Speaker may be removed from his office at any time with or without cause by the affirmative vote of two-thirds of the entire House of Delegates.

11.12 In the event of the absence of the Speaker or inability of the Speaker to serve, the Vice-Speaker shall succeed to his powers and duties. In the event of the death, resignation or removal of the Speaker, the Vice-Speaker shall automatically succeed to the office of the Speaker for the unexpired term.

ARTICLE XII

COUNCIL

12.1 Between sessions of the House of Delegates the affairs of the Association shall be managed by a Board of Directors which shall be known as the Council, and the members of which shall be known as Councilors. It shall have authority to do and perform all acts and functions which the House of Delegates might do or perform not inconsistent with the Articles of Incorporation and By-laws or with any action taken by the House of Delegates.

12.2 Each Councilor shall be designated to represent one Councilor District. The House of Delegates shall, upon recommendation of the Council, establish a number of Councilors, which shall never be less than three, group the component societies into Councilor Districts, and set the number of Councilors designated to represent each Councilor District.

12.3 Each Councilor shall serve for a term of three years beginning on the first of the calendar year following the date of his election. The terms of all the Councilors shall be so arranged that, as nearly as possible, one-third shall be elected each year.

12.4 At each annual meeting the House of Delegates shall elect a Councilor to fill the term of each Councilor whose term expires at the end of that year. At least one month in advance of each annual meeting of the House of Delegates, the Delegates in each Councilor District for which a Councilor is to be elected shall hold a caucus at which they shall select a nominee for the office of Councilor and the name of such nominee shall be submitted to the House of Delegates for its consideration. The Speaker shall designate one component society Secretary within each Councilor District concerned to assume the responsibility for setting the date, place and time for such caucus. The Delegates present at such caucus shall select a Chairman who shall present to the House of Delegates the name of the nominee so selected. At the annual meeting of

CONSTITUTION AND BY-LAWS

The House of Delegates other nominations for the office of such Councilor may be made from the floor. No person may be nominated for or elected to the office of Councilor for any Councilor District unless he be a member of the component society or one of the component societies in such Councilor District and an active member of the Association.

12.5 Any Councilor may be removed from his office at any time with or without cause by the affirmative vote of two-thirds of the entire House of Delegates.

12.6 The President, the first Vice-President, the President-elect, the last past President, the Secretary, the Treasurer, the Speaker and the Delegates and Alternate Delegates to the American Medical Association shall be ex officio members of the Council but without the right to vote.

12.7 A majority of the voting members of the Council shall constitute a quorum for the transaction of business, provided, however, that if a vacancy exists by reason of death, resignation or otherwise, a majority of the remaining Councilors shall constitute a quorum for the purpose of filling such vacancy.

12.8 If there be any vacancy in the office of any Councilor or in any office of the Association or in any office of Delegate or Alternate Delegate to the American Medical Association by reason of death, resignation or otherwise, the Council may fill such vacancy for a period ending at the expiration of the term of such office or the next annual meeting of the House of Delegates, whichever shall first occur.

12.9 The Council, or such members thereof as may be designated by the Chairman, shall serve as the Finance Committee of the Association and shall present to each annual meeting of the House of Delegates a report of the Finance Committee. The Chairman shall have authority to appoint three members of the Council to serve as a subcommittee on finance to make recommendations to the Council.

12.10 At each annual meeting of the Council, the Council shall elect a Chairman to serve until the next annual meeting of the Council and until his successor is elected and qualified. At each annual meeting of the Council shall also elect a Clerk who, in the absence of the Secretary of the Association, shall keep a record of the proceedings of the Council.

12.11 The Council may, by order of the Chairman or by the vote of a majority of its voting members present, go into executive session, such executive session to be limited to only the voting members and such others as may be invited to remain by the Chairman or by a majority of its voting members.

12.12 The Secretary of the Association shall keep a record of all the proceedings of the Council, except

those from which he is excluded by reason of the same being an executive session.

12.13 The Chairman of the Council shall present to each annual meeting of the House of Delegates a report of the activities of the Council during the preceding year.

12.14 At each annual meeting of the House of Delegates the Council shall present a list of nominations for Delegates and Alternate Delegates to the American Medical Association. Additional nominations may be made from the floor.

12.15 The Council shall have authority to employ such persons, including an Executive Secretary, as it deems necessary to carry out the work of the Association and to employ such independent public accountant or firm of independent public accountants as it deems appropriate to audit the accounts of the Association. It shall have authority to determine the compensation to be paid to any of the foregoing.

12.16 The Council shall provide for and superintend the publication and distribution of all proceedings and transactions of the Association and of Minnesota Medicine. It shall appoint the editor and members of the Board of Editors of Minnesota Medicine and determine the compensation to be paid to each.

12.17 All bonds, stocks, mortgages, contracts, notes, debentures and other negotiable instruments and all other real and personal property, of every nature whatsoever, that may be owned or held by the Association may be sold, transferred or assigned, in accordance with the order of the Council. The Chairman of the Council or the President of the Association and the Treasurer, Secretary or Executive Secretary of the Association are empowered to, and shall, execute such instrument or instruments of sale, transfer or assignment as may be necessary to affect or consummate any such sale, transfer or assignment in accordance with the order of the Council. The Chairman of the Council or the President of the Association and the Treasurer, Secretary or Executive Secretary are authorized to execute any and all contracts of the Association.

12.18 Each Councilor shall supervise the component societies in his Councilor District. He shall visit the counties in his Councilor District when necessary for the purposes of organizing component societies where none exist, of inquiring into the conditions of the medical profession in such societies, of improving and increasing the activities of the component societies and their members, and of acting as peacemaker for his Councilor District. The actual expenses incurred by each Councilor and each Councilor-elect in connection therewith and in connection with attendance at special meetings of the Council shall be paid to such Councilor against a properly itemized statement. Nothing contained herein shall be construed to authorize payment to a Councilor of his expenses while in attendance at the annual meeting of the Association.

CONSTITUTION AND BY-LAWS

ARTICLE XIII

COMMITTEES

13.1 The Council shall have authority to create such committees as it deems appropriate and to establish the authority and duty of each committee. There shall be two classes of committees, to-wit: scientific and non-scientific. The President and the Secretary of the Association shall be ex officio members of all committees. All committees are responsible and shall report to the Council, except during periods when the House of Delegates is in session. Each committee shall at each annual meeting of the House of Delegates make a report to the House of Delegates of its activities during the preceding year.

13.2 The scientific committees shall be appointed by the President with the approval of the Council.

13.3 The non-scientific committees shall be appointed by the Council.

13.4 The members of each committee shall be appointed for a term of one year, commencing on the January 1 following the date of their appointment unless otherwise stipulated by the appointment.

ARTICLE XIV

OFFICERS

14.1 The officers of the Association shall consist of a President, a President-elect, two Vice-Presidents, a Secretary and a Treasurer. At each annual meeting the House of Delegates shall elect a President-elect, a first Vice-President, a second Vice-President, a Secretary and a Treasurer, each of whom shall be an active member of the Association. No person shall be elected to the office of President-elect who has not been a member of the Association for at least two years prior thereto.

14.2 The President-elect shall serve as such until the first of the calendar year following his election, at which time he shall become President and serve as such for a period of one year, and thereafter until his successor is elected and qualified. Each other officer shall serve for a period of one year commencing on the first of the calendar year following his election and thereafter until his successor is elected and qualified.

14.3 Any officer of the Association and any Delegate or Alternate Delegate to the American Medical Association may be removed by the affirmative vote of a majority of the entire Council.

14.4 In the event of the absence or inability to serve of the President, the first Vice-President shall succeed to his powers and duties.

14.5 The President shall preside at all meetings of the Association, except at meetings of the House of Delegates or of the Council. He shall be an ex officio member of the House of Delegates and the Council, but without the right to vote. He shall appoint, with the approval of the Council, all scientific committees. He shall deliver an annual address at the annual meet-

ing of the Association and perform such other duties as may be delegated to him by the House of Delegates or the Council.

14.6 The President-elect shall be an ex officio member of the House of Delegates and of the Council but without the right to vote.

14.7 The Vice-Presidents shall assist the President in the discharge of his duties in such manner as he may authorize and shall perform such other duties as may be conferred upon them by the Council. The first Vice-President shall be an ex officio member of the House of Delegates and the Council, but without the right to vote.

14.8 The Treasurer shall give bond in such sum as the Council may require and the expense of such bond shall be borne by the Association. He shall be an ex officio member of the House of Delegates and of the Council, but without right to vote. He shall authorize the disbursement of funds out of the treasury upon the written order of the Chairman of the Council and the Secretary of the Association and shall, when authorized by the Council, establish one or more special bank accounts upon which persons other than those named above may be authorized to draw. At each annual meeting he shall render to the House of Delegates an accounting of the receipts and expenditures of the Association during the preceding fiscal year of the Association and his accounts shall be subject to such examination as the House of Delegates may order. The Treasurer may delegate any of the powers and duties herein conferred upon him to any assistant or assistants that the Council may employ. The amount of his salary shall be fixed by the Council.

14.9 The Secretary shall give bond in such sum as the Council may require and the expense thereof shall be borne by the Association. The Secretary shall attend meetings of the Association, of the House of Delegates and of the Council and shall keep minutes of the proceedings thereof in a separate record book for each. He shall be ex officio Secretary of the Council and of the House of Delegates, but without the right to vote.

The Council may appropriate moneys of the Association to be placed in one or more revolving funds maintained by the Secretary and from which the Secretary may make such disbursements for purposes of the Association as he deems necessary.

The Secretary shall provide for the registration of all members and delegates at annual meetings of the Association and shall act as General Manager of the annual meetings. Subject to the supervision and direction of the Council, he shall arrange for and have charge of the scientific and technical exhibits at each annual meeting and collect and deposit in a special fund amounts received in connection therewith. He shall be authorized to draw on such fund for expenses in connection with each annual meeting, but at the conclusion thereof shall turn the balance of such fund over to the Treasurer.

The Secretary shall notify members of meetings, offi-

ers of their election and committees of their appointments and duties. He may delegate any of the powers and duties herein conferred upon him to any assistant or assistants that the Council may employ. He shall supply each component society with the necessary blanks for making its annual report, keep an account with each component society showing the dues, assessments and other charges payable by each member thereof, collect the same and turn the same over to the Treasurer. The amount of his salary shall be fixed by the Council.

The Secretary shall, with the co-operation of the secretaries of the component societies, keep a register of all physicians licensed to practice in the State of Minnesota by counties, noting therein the status of each physician in relation to his component society, and upon request shall transmit a copy of this list to the American Medical Association.

14.10 All books, records and papers belonging to the Association shall be maintained in the principal office of the Association.

ARTICLE XV

AMENDMENTS

15.1 These By-laws may be amended at any special or annual meeting of the House of Delegates by the affirmative vote of a majority of the Delegates voting thereon; provided that the Council by resolution has proposed such amendment and directed that it be submitted to the House of Delegates for adoption; and provided that written notice of such meeting, stating the purpose, shall have been given not less than five nor more than thirty days prior to the time fixed therefor to each Delegate and Alternate Delegate of the House of Delegates and to each Councilor and officer of the Association, regardless of his voting rights.

Minnesota State Medical Association

104th Annual Meeting

Preliminary Program Plans

The Committee on Scientific Assembly of the Minnesota State Medical Association has announced preliminary plans for the 104th annual meeting of the Association to be held May 13, 14, and 15, 1957, in St. Paul. A complete program will appear in the April issue of MINNESOTA MEDICINE.

Dr. J. A. Bargaen, Rochester, president of the state association, is general chairman of the Committee on Scientific Assembly. Other members include Dr. R. H. Wilson, Winona, past president, and R. R. Rosell, St. Paul, executive secretary. Dr. Donald S. Amatuzio, Minneapolis, and Dr. W. S. Neff, Virginia, represent the section on medicine; Dr. R. P. Buckley, Duluth, and Dr. J. P. Medelman, St. Paul, the section on specialties; and Dr. B. M. Black, Rochester, and Dr. W. O. Finkenburg, Winona, the section on surgery. Dr. Wallace P. Ritchie, St. Paul, is general chairman of the committee on local arrangements.

The tentative program is as follows:

MONDAY, MAY 13

9:00 A.M.—Panel Discussion on "Heart Disease in Pregnancy," sponsored by the Minnesota Heart Association
DR. RODNEY F. STURLEY, St. Paul, *Chairman*
DR. JOHN F. BRIGGS, St. Paul, *Moderator*

"Surgery of the Heart in the Pregnant Patient"
DR. CHARLES P. BAILEY, Philadelphia, Pennsylvania

"Medical Aspects"
DR. JAMES METCALFE, Boston, Massachusetts

"Control Of Hypertension"
DR. NICHOLAS AASLI, Los Angeles, California

"Obstetric Problems"
DR. I. H. KAISER, University of Minnesota

10:15 A.M.—Intermission

11:00 A.M.—RUSSELL D. CARMAN MEMORIAL LECTURE
PROF. DR. HANS HEINRICH BERG, Hamburg, Germany

12:15 P.M.—ROUND TABLE LUNCHEONS

2:00 P.M.—Panel Discussion, "The Acute Abdomen"
DR. HENRY L. BOCKUS, Philadelphia, Pennsylvania, *Moderator*
DR. N. LOGAN LEVEN, St. Paul
DR. LEO G. RIGLER, University of Minnesota
DR. HARRY B. NEEL, Albert Lea
DR. J. C. CAIN, Rochester

3:15 P.M.—Intermission

4:00 P.M.—"Iatrogenic Disorders in Gastroenterology"
DR. HENRY L. BOCKUS, Philadelphia

6:00 P.M.—Special Dinners

TUESDAY, MAY 14

9:00 A.M.—Panel Discussion, "Functional Disorders"
"Gastrointestinal Aspects," DR. R. S. YLVIKAKER, Minneapolis
"Gynecology," DR. E. A. BANNER, Rochester
"Dermatology," DR. F. T. BECKER, Duluth
"Tension States," DR. H. O. BECK, St. Paul
Question-and-answer period

10:00 A.M.—Presidential Address
DR. J. A. BARGEN, Rochester

10:15 A.M.—Intermission

11:00 A.M.—ARTHUR H. SANFORD LECTURE
"Essentials of Endometrial Pathology"
DR. ARTHUR T. HERTIG, Boston, Massachusetts

12:15 P.M.—ROUND TABLE LUNCHEONS

2:00 P.M.—Panel Discussion, "Palliative Treatment of Cancer"
"Use of Hormones," DR. B. J. KENNEDY, University of Minnesota
"By Neurosurgery," DR. R. L. MERRICK, St. Paul
"Radiation Therapy," DR. DONALD S. CHILDS, Rochester
"By Drugs," DR. JOHN LUNDY, Rochester

3:15 P.M.—Intermission

4:00 P.M.—MINNESOTA DIVISION, AMERICAN CANCER SOCIETY LECTURE
"Chemotherapy of Cancer"
DR. C. P. RHOADS, Sloan-Kettering Institute for Cancer Research, New York City

7:00 P.M.—Annual Banquet
Speaker: REAR ADMIRAL HYMAN G. RICKOVER, Washington, D. C.
Presentation of Fifty Club, Special Awards

PRELIMINARY PROGRAM

WEDNESDAY, MAY 15

9:00 A.M.—NORTHWESTERN PEDIATRIC SOCIETY LECTURE

"Endocrinopathies in Children"

DR. VINCENT KELLEY, Salt Lake City, Utah

9:40 A.M.—MINNESOTA MEDICAL FOUNDATION LECTURE

"The Practical Appraisal of Liver Function"

DR. CECIL WATSON, University of Minnesota

10:15 A.M.—Intermission

11:00 A.M.—"The Menopause and Thereafter"

DR. WILLIAM H. MASTERS, Associate Professor of Obstetrics and Gynecology, Washington University School of Medicine, St. Louis, Missouri

11:30 A.M.—MINNESOTA ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY LECTURE

"Functional Disorders of the Nose"

DR. C. STEWART NASH, Rochester, New York

12:15 P.M.—ROUND TABLE LUNCHEONS

2:00 P.M.—Panel Discussion, "Management of Acute Injuries"

DR. CLAUDE HITCHCOCK, Minneapolis, Moderator

"Shock," DR. RALPH SMITH, Veterans Hospital, Minneapolis

"Head," DR. HAROLD F. BUCHSTEIN, Minneapolis

"Chest," DR. LYLE TONGEN, St. Paul

"Vascular Injuries," DR. JOHN IVINS, Rochester

The sessions will be held at the St. Paul Municipal Auditorium; special dinners and luncheons will be primarily at Hotels Saint Paul and Lowry in St. Paul.

The Woman's Auxiliary to the state medical association will hold its annual meeting at the same time with headquarters at Hotel Lowry. Mrs. W. P. Gardner and Mrs. W. P. Ritchie, St. Paul, are co-chairmen for Auxiliary activities.

HIGHWAY DEATH TOLL CALLS FOR "TEAMWORK"

As the accident and death toll from highway auto accidents mount, it takes a "team approach" by doctors to care adequately for many of the accident victims.

This is the report of a St. Joseph, Mo., radiologist, Dr. Jacob Kulowski. He has made a detailed study of the x-ray aspects of car accidents and reported his conclusions in the January, 1957, issue of *The American Journal of Roentgenology, Radium Therapy and Nuclear Medicine*.

"Medical concern is growing in regard to the increasing toll of life and limb being exacted on our highways. With the advent of techniques and methods of studying these accidents, the evolution of medical participation may be expressed as advancing from a 'do-it-yourself' attitude to a 'do-it-together' plan of medical action," Dr. Kulowski pointed out.

Some of his other conclusions:

Drivers with cervical arthritis are more prone to rear-end and impacts from an angle—especially at intersections. It is possible that the circular and rocker action of the cervical spine, which is needed to meet these danger cues at intersections, is inadequate in some of these drivers. That is, movement of the neck to supplement the field of vision to either side is inadequate.

Some persons, who might cringe from a mouse, have not acquired a sense of the dangerousness of some aspects of motoring; these people assume an imaginary protection which doesn't exist.

Radiologists can improve first aid by urging against poor handling of simple fractures which sometimes causes a compound fracture.

Some statistics revealed in Dr. Kulowski's report:

Among motoring casualties who reach a hospital, 45 per cent are hurt to a minor degree; 45 per cent are more severely injured; and 10 per cent are severely or dangerously hurt.

Of those 10 per cent severely hurt, about 15 per cent die outright at the scene of the accident; of those severely hurt who reach the hospital, about two-thirds die within the first forty-eight hours, the rest at varying times.

The immediate deaths are due to primary, irreversible shock to vital functions. Deaths which occur soon afterwards are also due to primary shock.

Plan Now to Attend the 104th Annual Meeting of the Minnesota State Medical Association, Saint Paul, May 13, 14 and 15, 1957.

Medical-Legal Opinions

JULE M. HANNAFORD, Legal Counsel
Minnesota State Medical Association

These opinions were prepared by Jule M. Hannaford, legal counsel for the Minnesota State Medical Association. Mr. Hannaford is a partner with the firm of Dorsey, Owen, Barker, Scott and Barber, Minneapolis.

TEST FOR ALCOHOL

When a person's competence to operate an automobile is questioned, police officers frequently request specimens or blood samples of the person and analyses for alcoholic content. This raises various legal problems.

The problem arises generally when a person is brought by a police officer to a physician's office or to a hospital with the request that a specimen or blood sample be taken and that a report of the analysis thereof be given to the police officer. The request may be made and the specimen or blood sample taken by a physician or some technician who does not hold a degree of a Doctor of Medicine.

Two legal principles are involved in such a situation. The first has to do with the right of the physician or technician to take a specimen or a blood sample. The second has to do with the admissibility in evidence of an analysis of the specimen or blood sample in a prosecution for drunken driving. Each will be discussed in turn and certain suggestions for handling such a situation will be advanced.

I

Neither a physician nor a technician may apply a medical procedure to a person without the person's consent. A physician or technician who does so commits an assault and can be held responsible for the resulting damages. The taking of a specimen or a blood sample is a medical procedure within the foregoing rule and cannot, therefore, be done without risk unless consent is first obtained.

The foregoing conclusion is not altered by reason of the fact that the taking of the specimen or the blood sample was done at the request of a police officer. The constitution prohibits unreasonable searches and seizures and also prohibits compelling a person to give evidence against himself. A police officer who violates these prohibitions and the persons who assist him may be committing a crime and can be held responsible for the resulting damages. The taking of a specimen or a blood sample without the consent of the person from whom they are taken would prob-

ably be considered a violation of these prohibitions and could not, therefore, be done without risks unless consent is first obtained.

The consent that will protect either a physician or a technician may be either actual or implied. Actual consent results when the person gives his consent orally or in writing. Implied consent results when the person cooperates with the physician or technician by voluntarily giving a specimen or permitting a blood sample to be taken.

II

The Minnesota Legislature at its 1955 session passed a law which states that in prosecution for drunken driving "the court may admit evidence of the amount of alcohol in the person's blood taken voluntarily within two hours of the time of arrest as shown by medical or chemical analysis of his breath, blood, urine or saliva." Section 169.12 Minn. Stats. The statute goes on to state that .05 per cent or less by weight of alcohol in a person's blood is *prima facie* evidence he was not drunk, .15 per cent or more is *prima facie* evidence that he was drunk, and more than .05 per cent but less than .15 per cent is relevant but not *prima facie* evidence as to his condition.

Prior to the enactment of this statute it was not clear whether an analysis of a specimen or a blood sample which had been obtained without the defendant's consent could be admitted in evidence. The statute by using the phrase "taken voluntarily" would seem to make it clear that such an analysis is not admissible unless the defendant's consent has been obtained. However, it is not clear how extensive the consent must be. Is it sufficient if the person voluntarily gives a specimen or permits the taking of a blood sample? Or must he also consent to having an analysis made? Or before he consents must he be told that the analysis will be for alcoholic content and will be given to the police and consent to this as well? The statute is so new that the Minnesota courts have not as yet answered these questions and the courts of other states are divided in their answers. It does, however, seem clear that if the defendant consents to the taking of the specimen or blood sample, to the making of an analysis for alcoholic content, and to the giving of the

analysis to the police officer, then he has no grounds under the statute to object to the admission of the analysis.

The defendant might also object to the admission of the analysis on the ground that it is a privileged communication. Section 595.02 of Minn. Stats. provides in part as follows:

"A licensed physician or surgeon shall not, without the consent of a patient, be allowed to disclose any information or any opinion based thereon which he acquired in attending the patient in a professional capacity, and which was necessary to enable him to act in that capacity."

This statute relates to information obtained by a licensed physician or surgeon. Therefore, if the specimen or blood sample is taken and analyzed by a technician and if no physician or surgeon directs the technician or treats the defendant, the defendant probably could not object to the admission of the analysis on the basis of the foregoing statute. Moreover, the statute prohibits the disclosure of only such information as is necessary to enable a physician or surgeon to treat the defendant in a professional capacity. Therefore, if the defendant is not injured and does not need treatment for alcoholism or some other condition, the information would not have been acquired while attending the defendant and the defendant probably would not be in a position to claim privilege. It would, therefore, seem that a defendant could claim the benefits of the foregoing statute only if the specimen or blood sample were taken by a physician or surgeon or under his direction and were so taken for the purpose of treating the defendant in a professional capacity.

III

As a result of the foregoing we are of the opinion that when a potential defendant is brought to a physician or a technician by a police officer with the request that a specimen or blood sample be taken and analyzed, the physician or technician should not do so unless the potential defendant is informed that the specimen or blood sample will be analyzed for alcoholic content and consents not only to the taking of the specimen or the sample

but also to its analysis and the delivery of a copy of the analysis to the police officer. The only exception to this general rule should be in cases where because of injury, intoxication or some other condition the physician believes that medical treatment is required and that a specimen or blood sample is needed for such purpose. In such cases it is, of course, proper to take a specimen or blood sample, but we believe the analysis should not be turned over to the police until the patient has recovered to a sufficient extent so that there can be no question as to his rationality, until he has been advised of the purpose for which the analysis may be used and until he consents thereto.

We have two further suggestions. First, if the physician or technician is given a choice between taking a specimen or a blood sample, we would recommend he take a specimen because the patient will normally co-operate in its taking and will, therefore, have difficulty in arguing he did not impliedly consent. Secondly, while a physician or technician would run little risk if the police officer took the specimen or blood and if the physician or technician limited his activity to making the analysis, we would not suggest such a solution when the taking is done in the physician's office or in a hospital. If a proper consent is not obtained in such a case, we fear the physician or the hospital would be held equally liable with the police officer on a conspiracy theory because his or its facilities were used by the police officer.

To obviate the problems outlined above, several bills have been introduced in the current session of the Minnesota Legislature which require a person, when applying for a driver's license, to consent in writing to the taking of a blood sample or a specimen if arrested for drunken driving. If such a bill is passed, it will in time relieve the physician from the necessity of bothering with consents each time he is to take a blood sample or specimen. However, as Minnesota drivers' licenses need be renewed only every four years, it will be at least four years after the bill is passed before all Minnesota drivers have signed such a consent. Moreover, it should be remembered that non-residents who do not have a Minnesota driver's license will not have signed such a consent.

History has proved time and time again that tuberculosis recedes wherever social and economic conditions assure for man an environment conducive to physical well-being and happiness. It has often been pointed out that the mortality caused by tuberculosis, and by other microbial diseases as well, had begun to decrease before the campaigns based on the germ theory had been put into effect. The campaign against infection

began with the great public health reforms. The early pioneers of the public health movement were little concerned with germs, but they knew that an effective way to combat consumption and other "infectious fevers" was to assure for each citizen good air, pure water, adequate food, and pleasant and happy surroundings, both at work and at play.—RENE J. DUBOS, Ph.D., *Nat. Tuberc. A. Tr.*, May, 1954.

Meetings and Announcements

STATE

MINNESOTA STATE MEDICAL ASSOCIATION, 104th annual meeting, Saint Paul, May 13, 14 and 15, 1957.

NATIONAL

American Congress of Physical Medicine and Rehabilitation, thirty-fifth annual scientific and clinical session, Los Angeles, September 8-13, 1957.

WORLD CONGRESS OF GASTROENTEROLOGY

The World Congress of Gastroenterology will be held May 25-31, 1958, at the Sheraton Park Hotel in Washington, D. C. An attendance of about 3,000 physicians is expected, with representatives from most of the nations outside the Iron Curtain. Subjects to be discussed include peptic ulcer, malabsorption in sprue syndrome, nutrition and its effects on the liver and pancreas, intestinal infection and infestation and cancer of the stomach. Inquiries for further information should be addressed to Dr. H. M. Pollard, University Hospital, University of Michigan, Ann Arbor, Michigan. Dr. Pollard is secretary-general of the Congress.

TENTH ANNUAL POSTGRADUATE COURSE ON DISEASES OF THE CHEST

The Tenth Annual Postgraduate Course on Diseases of the Chest, sponsored by the Council on Postgraduate Medical Education of the American College of Chest Physicians and the Laennec Society of Philadelphia, will be held April 1-5, 1957, at the Bellevue-Stratford Hotel, Philadelphia, Pennsylvania. A fee of \$75.00 will be charged for the course, which gives forty-two hours of informal credit toward postgraduate education requirements of the American Academy of General Practice. Credits will also be given to applicants for Fellowship in the American College of Chest Physicians.

General subjects to be discussed in this course are: Nontuberculous diseases, Physiology, Tuberculosis, Cancer of the Bronchi and Lungs, Radiology, Cardiology, the Esophagus, and Esoteric Diseases. Five round table luncheon meetings and a dinner meeting will be held.

Further information may be obtained from the American College of Chest Physicians, 112 East Chestnut Street, Chicago 11, Illinois.

CONGRESS OF PHYSICAL MEDICINE AND REHABILITATION TO MEET AT ROCHESTER

The next meeting of the Midwestern Section of the American Congress of Physical Medicine and Rehabilitation will be held in Rochester, Minnesota, at the Mayo Clinic, May 3-4, 1957. In addition to a scientific session there will be tours of the various facilities in the Mayo Clinic. Those interested in attending should contact Dr. Gordon M. Martin, Section of Physical Medicine and Rehabilitation, Mayo Clinic, Rochester, Minnesota.

STATE MEDICAL ASSOCIATION OFFERS SCIENCE FAIR SCHOLARSHIP

The Minnesota State Medical Association is sponsoring a \$225 scholarship for the best exhibit in the biologic sciences by a Minnesota high school student at the 1957 state science fairs. The purpose of these fairs is to increase interest in the study of science at the high school level.

RURAL MEDICAL SCHOLARSHIP AWARDED TO ANOKA MAN

The 1957 rural medical scholarship award sponsored by the Minnesota State Medical Association has been presented to Vincent R. Hunt, age twenty-two, Anoka, a freshman at the University of Minnesota Medical School. Hunt graduated with honors from St. John's University, Collegeville, in May, 1956. He is one of seven children and the son of Mrs. V. R. Hunt, a teacher in the Anoka school system, and the late Mr. Hunt, former Northfield, Minnesota, high school coach.

Under the provisions of the scholarship, Hunt will receive \$1,000 each year for four years. In return he must promise to practice medicine in a town of 5,000 or less population for five years after his graduation. He is the fifth rural scholarship recipient; the first, Richard Engwall, Winthrop, has received his medical degree.

MEDICAL CONTINUATION COURSES AT THE UNIVERSITY OF MINNESOTA

March 18-20	Pediatrics for General Physicians
March 21-23	Obstetrics for Specialists
April 6	Trauma for General Physicians
April 8-10	Radiology for General Physicians
April 11-13	Allergy and Chest Disease for General Physicians
May 6-10	Introduction to Electrocardiography for General Physicians
May 13-17	Proctology for General Physicians
May 23-25	Surgery for Surgeons

For further information concerning the above courses, write to the Director, Department of Continuation Medical Education, 1342 Mayo Memorial, University of Minnesota, Minneapolis 14, Minnesota.

STATE OPHTHALMOLOGISTS URGED TO AID FIREARMS SAFETY TRAINING PROGRAM

During the past year and a half the Minnesota Department of Conservation has been organizing and administering a statewide course of instruction in firearms safety to Minnesota youngsters between the ages of ten and sixteen.

This program, which was established during the 1955 session of the state legislature, requires the training of youths in this age group who wish to participate in shooting or hunting activities. The program is carried out on a local community basis through a volunteer corps of trained instructors and through contributed monies from civic groups, organizations and private concerns and through local training fees levied on the youngsters.

Mr. Lee Kuluvar, the state coordinator for the program, has informed the Minnesota State Medical Association that the state is trying to encourage visual checks for the youth trainees taking the instruction. In a study made on the vision of hunters and other shooters who had accidentally shot other individuals during 1953, it was found that the visual capacity of an individual has a definite bearing on firearms accidents. The most revealing fact was that the greater percentage of these "shooters" did not know of their handicap. Therefore, the state feels that to acquaint these individuals with their vision limitations could very well have a direct bearing on the accident rate.

As a noncompulsory part of the training program the students are being encouraged to have their eyes checked. Because it is a voluntary community project for the good of the youth and the citizens of the community, state medical association members who are ophthalmologists are being asked to cooperate in this project.

The visual checks are not too involved and should be made in the following areas: visual acuity, muscle balance, depth perception, color vision and field of vision. The youngster should then be informed whether or not his vision is or is not adequate in all areas, so that he can report this to his parents. It is hoped that the parent will take the necessary steps for correction of correctable deficiencies. If the deficiency cannot be corrected, the parents will at least know of the limitation.

For the past three autumns the state has also tried to encourage these free checks for the adult hunters. These programs are generally set up by some sponsoring organization and through the volunteer help of licensed examiners. This coming fall it is hoped that this community adult hunter checking program will become even more widespread. Any assistance on the adult program will also be greatly appreciated by the state firearms safety program.

Menopausal symptoms in 100 patients between the ages of thirty-five and sixty-two years were treated with 6 mg. daily of methallenestril (Vallestril), a synthetic estrogen; a contra-test group of twenty patients received a placebo. Good or fair results were obtained in 91 per cent of the test group in contrast to 15 per cent in the control patients.

The dosage schedule ran for thirty days, at which time medication was interrupted for two weeks and the need for a second course determined by the return or absence of symptoms. No patient was given more than three such courses in any four-month period.

Vaginal smears taken from certain patients objectively corroborated the subjective findings. An estrogenic response was evident after ten to fourteen days of medication and persisted for sixteen to thirty days after cessation of therapy.

The dosage used did not cause withdrawal bleeding or any other untoward effects but generally gave a feeling of well-being. As is usual with all estrogens, the warning against unnecessarily prolonged medication offered.—Goldfarb, A. F., and Napp, E. E.: J.A.M.A. 161:616 (June 16) 1956.

Woman's Auxiliary

MID-WINTER BOARD MEETING HELD JANUARY 23

The Midwinter Board meeting was held January 23, 1957, at the Minnesota Club, St. Paul, with forty-eight members present. Mrs. L. P. Howell presided. Mrs. Robert Flanders, president of the Woman's Auxiliary of the American Medical Association, was a guest at the meeting and spoke following the luncheon. Mrs. William Finkelburg, Winona, led the group in the pledge of loyalty to the Auxiliary. Mrs. E. R. Hudec called roll and read the minutes of the fall meeting; Mrs. W. B. Stromme read the treasurer's report. Mrs. J. M. Waugh, corresponding secretary, read letters from Mrs. P. J. Pankratz, who, with her husband, is now working at the Mennonite Mission in Taiwan, Formosa, and from Mrs. C. L. Oppegaard, president-elect, who was in Phoenix, Arizona, celebrating the advent of a new grandson. Following is a summary of the reports of officers and committee chairmen:

Mrs. Reuben Erickson, first vice-president, reported on the TB essay awards. The Auxiliary again co-sponsored the contest, and she presented the awards to the winners over WCCO-radio (Minneapolis) in December. She told of her activities on the geriatrics commission and urged Minneapolis women to become acquainted with the Council for Senior Citizens and its work with the aged people of Hennepin county.

Mrs. H. F. Polley, Rochester, described the regional meeting in Region One and Mrs. M. I. Hague, Clarkfield, reported on meetings in Region Three. Mrs. Hague stated that a full report of the fall school of instruction was given at a regional luncheon meeting, that she had spoken at a meeting of the Lyon-Lincoln Auxiliary, and that her county groups had difficulty filling out the blanks for the nominating committee.

Mrs. L. Raymond Scherer spoke on the problems of Region Six, which includes Hennepin county. She also gave a special, detailed, excellent report on Medicare, the program for dependents of military service personnel. These individuals are now receiving free diagnostic and in-hospital care from civilian physicians, with the state medical association as fiscal agent. She stressed the importance of the fact that this plan does allow for free choice of physician and the fact that doctors have their own societies as fiscal agents and their own grievance committees to handle complaints. Since Minnesota does not have a large military personnel, our administration problems will not be as great as elsewhere.

Mrs. Philip Arzt reported for Mrs. W. P. Gardner, state legislative chairman. She listed several bills of special interest to the medical profession which will be debated in the current Minnesota legislative session. These concern the status of Minnesota osteopaths, sanitary conditions and inspection methods in restaurants, salaries of Minnesota public health officials and a new

medical examiner system to augment the county coroner set-up. Mrs. Flanders talked about national legislation: the Medicare program, the Jenkins-Keogh plan to establish a retirement fund for the self-employed, the disability amendment to the social security act passed in the last session, the federal reinsurance program, and the Hill-Burton hospital construction program. Both she and Mrs. Arzt urged members to read the legislative material in *Bulletin*. Mrs. Howell asked that everyone read Dr. Dwight Murray's speech, "Freedom in Medical Practice," copies of which were distributed, as it presents a good over-all picture of the trends in medical practice in the United States. It underlines the basic principles which we must hold on to, not because of self-interest, but because of "what is best for all Americans and our free society."

Mrs. E. H. Soule, Allied Careers chairman, told of Red River Valley's decision to help a widow study anesthesiology. She said she had new material on careers which she will send out to the county auxiliaries. Mrs. C. E. Carlson, Alexandria, reported on a successful and unique Career Days program held in her city for high school students.

AMEF chairman, Mrs. W. E. Wellman, in a written report, urged 100 per cent participation of county groups and expressed gratification with the response to the fund drive this year. She suggested special projects such as silver teas and bake sales to raise money if treasuries are low. Deadline date is May 1. Mrs. Flanders encouraged members to use the "In Memoriam" cards for AMEF. Medical Education week could well present an opportunity to remind the public of the high standards of our medical schools and the increasing costs of medical education.

Mrs. Ralph Eckman spoke of the value of *Bulletin*. Mrs. John Cameron, Cancer chairman, asked that each county make good use of the cancer education kits provided for all the Auxiliaries. She was enthusiastic about the cancer society's workshop which she attended last fall. Civil Defense chairman, Mrs. J. A. Cosgriff, distributed various leaflets with good program material on defense. She reported on her attendance at a civil defense meeting in St. Paul where plans were made to appoint civilian disaster chairmen in schools. They would take over in case of emergency.

Mrs. C. E. Carlson, editor of the *Minnesota Gopher Doctor's Wife*, discussed the expense of publishing the newsletter and invited comments about it. All were enthusiastic about the development of the publication, its new format, its increased news content, its personal tone. Putting out a six-page issue of four issues a year would be desirable because of the wealth of material worthy of printing, but this is contingent upon costs. Mrs. Carlson thanked all members who have contributed items and ideas, asked for personal items of general

interest to our membership as well as stories about meetings and projects.

Health Days chairman, Mrs. Conrad Karleen, requests information about any health days that have been held or are planned.

Mental Health chairman, Mrs. William Gjerde, reminded members of 'mental health week in April and asked that each county auxiliary plan some type of activity for that week. She described "Milestones to Marriage," the series of pamphlets which has been sent to all auxiliaries for study with the hope that this valuable material can be used by high school students. She discussed ways of financing such an undertaking and listed the many organizations willing to help in the venture. Mrs. Francis McCarten, Stillwater, gave a special report on the emotionally disturbed children at the Hastings hospital, a moving story of what she herself had seen. She told of the volunteer work the Washington County Auxiliary has done for several years for the mentally ill in that institution. She encouraged members to do similar work wherever possible.

Mrs. A. B. Rosenfield, editor of our page in MINNESOTA MEDICINE, and Mrs. Leonard Arling, publicity chairman, both expressed thanks to all who have submitted material for their purposes. Mrs. L. R. Boies, printing chairman, announced that additional rosters are available at the state office and that the new constitutions will be printed soon. Mrs. Harold Wahlquist, who has worked on the revisions, discussed the editing of the constitution.

Program has received so much emphasis this year that Mrs. Arzt feels every group is aware of all phases of Auxiliary interest. She urged participation in the Science Fairs and asked for names of any new program chairmen who have been appointed. The Stearns-Benton idea of printing a year's program in advance was discussed. Mrs. Ezra Bridge, new president of Goodhue, stated that her society also makes long-range program plans and is now preparing a program booklet. Mrs. Howell said she felt programs need not always deal with Auxiliary work or medical matters but should always include something relating to Auxiliary interests—a series of announcements, a brief report of a meeting or a short talk.

Mrs. M. O. Wallace emphasized that everything doctors' wives do is really public relations work for their husbands: sponsoring TB contests, promoting career days, selling *Today's Health*—all these things. She stressed the fact that *Today's Health* is good PR material and that every doctor's wife should see to it that a copy is in her husband's office.

Mrs. Karl Anderson reported briefly on the fall school of instruction, the success and liveliness of the meeting and its good attendance. Mrs. H. P. VanCleve wants 100 per cent support from all counties for *Today's Health*. Minnesota's quota is 2,198. To date we have 524 subscriptions, well over last year at this time. This does not include subscriptions sent by the state medical association to all our legislators to acquaint them with the work done by the AMA in health education.

Nominating committee chairman, Mrs. Charles Merkert, thanked the counties for their cooperation in the work of her committee. The slate of officers will be read at the annual meeting.

In her president's report, Mrs. Howell cited the value of the interchange of ideas that a board meeting affords. She underlined the importance of securing a basic committee organization throughout the state and thinks there must be this committee structure if the county Auxiliaries are to function. She feels the basic "musts" are program, legislation, membership and *Today's Health*, and would like to add others! Such uniformity would result in a quickly mobilized, effective state Auxiliary. She regards as our greatest assets the fine support of the state medical association and our wealth of good leadership all over the state. Our greatest problem is the difficulty of relaying information from state board to general membership. "Black books" will be turned over to new chairmen and officers in May and Mrs. Howell asks that each include a copy of the year's report and suggestions for procedures.

Mrs. Karl Anderson described the activities of Hennepin auxiliary in establishing an Auxiliary for the wives of medical students at the University of Minnesota.

Mrs. Carlson reported on the new project, "Magazine for Friendship." She urged everyone to send at least one magazine a month abroad, to share our everyday information with people overseas. Mrs. Charles Froats, St. Paul, told of the success of a similar magazine project in another group to which she belongs.

Mrs. W. P. Ritchie announced the state convention dates: May 13, 14, 15, 1957. Place: St. Paul. Mrs. Howell announced that the national convention will be in New York, June 3-7, with headquarters at the Hotel Roosevelt. A block of rooms will be held for Auxiliary members until April 15. Mrs. Oppegaard will supply delegate cards at the annual state meeting.

Immediately after luncheon, Harold Brunn, assistant executive secretary of the state medical association, expressed his appreciation of the work of the Auxiliary and Dr. H. P. Sweetser, sixth district councilor, extended greetings from the Association. He spoke of the need for the Auxiliary and his gratitude for the many ways in which it helps the doctors. Mrs. Howell pointed out that Dr. Sweetser's mother was the first president of the state Auxiliary, serving three consecutive terms.

Mrs. Harold Wahlquist, past national president, won a round of applause when her outstanding contributions to our Auxiliary were listed by Mrs. Howell who had been writing a thumb-nail history of our group for *Bulletin* and found Mrs. Wahlquist responsible for much of our progress.

Featured speaker at the luncheon was Mrs. Robert Flanders, whose theme was: "Health Is Our Greatest Heritage." She cited Minnesota as one of the outstanding auxiliaries in the country, went on to explain how the Auxiliary, on a nation-wide basis, influences the health thoughts of the entire nation. She stresses that the Auxiliary must match steps with progress. Members must "be everywhere" to bring health education

to the public, be leaders in their communities in all health services to defend the nation against health ignorance. She believes it the duty of every doctor's wife to carry on this work. She said that the programs of the Auxiliary have proved their worth; the public respects and seeks the guidance of doctors' wives and the doctors' wives must not fail the doctors. She thinks it is up to the individual doctor's wife to study the health needs of her community; that health needs and tasks grow as technology advances are perfected. Each member should read *Bulletin* and *Today's Health* and work to increase membership for better service.

Mrs. Flanders believes education and service are the basic purposes of Auxiliary work. This coming year, she said, old projects will continue and new ones will be added, such as accident prevention—traffic safety in particular. Women should insist on safety devices on their cars and cooperate with safety organizations.

She stressed the great value of public relations. Every doctor's wife is doing PR work for her husband when she works on drives, in hospitals, in her church groups. She has a double role as a good wife and mother plus her role in health. The demands on a doctor's wife are many but so are the compensations for there is satisfaction in service to humanity.

EDITORIALLY SPEAKING

It would seem that the members of our society are just as resistant to the magazine *Today's Health* as they used to be toward *Hygeia*. In that day it was said this opposition was directed more against the editor, M. F., than any other factor, but he is long gone, the name, format and contents have been changed, and still there is a profound lack of interest in this fine propaganda medium.

It is agreed that we physicians have not been able to get our message across to the general public and their representatives in the federal and state legislatures. Well, maybe all do not agree with this statement, but the results would indicate that it is 99 44/100 per cent true. No longer can our officers and agents walk into a legislative committee and get the laws and actions that we request. Some yes, but many, no.

The individual physician is still well liked and respected by his patients, but physicians as a group are not liked by the man in the street, the voter. This has been confirmed by local and national polls too many times to be denied. And we are doing so little about it.

There are many reasons for this and complacency and lethargy are not the most important ones. Time is a factor, and strange as it may seem, there is a lack of knowledge as to the basic issues. Some physicians believe their job is just to practice medicine and take care of the sick. Some of these have gone so far as to state that they do not care too much about the economic and political atmosphere under which they have to work

as long as they can work. The latter may have no interest in any kind of propaganda medium, but most of the rest would if they thought there was something that would be effective.

Why is it that *Today's Health* has never been given the consideration it deserves as this agent? It is written for the laymen. It not only explains diseases and treatment in easily understood terms, but there is always something in every issue about the free and independent practice of medicine and its advantages to the general public and the health of the nation.

Some physicians have not wanted the magazine in their reception rooms because sometimes the opinions of the author disagree with his opinions and this leads to some patient-physician conflicts. Could be this is a valid consideration.

But let's think in terms of general public education. Where may we do the most good? One thinks at once of the youngsters of the nation, the future voters. How many have ever thought in terms of our schools? Teachers are very anxious to get the magazine because it is so valuable in teaching hygiene, public health and preventive medicine.

It would cost so little for each physician to buy one subscription for a school library, public, parochial, grade or high. Maybe two or three for the latter. If this were done, we would be getting our official health message across to all the kids who are going to grow up and have their own ideas, concepts and prejudices the rest of their lives. They are going to hear lots of adverse propaganda, be exposed to lots of reading matter that blasts us and engage in lots of talk about health and doctors.

If they know the answers, they could be a big help. If they don't, they are apt to believe all kinds of wild rumors and untruths.

How about it? Why not spend a couple of bucks to win some future friends?

G. WILSE ROBINSON, JR.

Although acceptance of specific therapy is a primary goal in the control of tuberculous disease, it is not the only one. In a broader sense modern medicine strives to return to society an individual free from organic disease, capable of assuming personal, family, and community responsibilities. A concept such as this implies that the individual will be physically able to work—that he will have been prepared for some vocation. Not every patient, of course, will need to acquire a new occupation. There are many, however, who never have had a vocation and will have to be trained in one compatible with physical status and aptitude.—SIDNEY H. DRESSLER, *Am. Rev. Tuberc.*, August, 1956.

While tuberculosis is obviously an organic disease, it is just as clearly a social disease, taking its greatest toll among low-income, unskilled laborers suffering from overcrowded housing and poor nutrition.—REMA LAPOUSE, M.D., *Am. J. Pub Health*, August, 1956.

In Memoriam

EDMUND WHITNEY ALGER

Dr. Edmund W. Alger, physician for Pillsbury Mills, Inc., for thirty-five years, died January 26, 1957. He was eighty years old.

Born in southeast Minneapolis, Dr. Alger graduated from the University of Minnesota Medical School in 1902 and practiced medicine for fifty-two years before his retirement.

He was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association. Dr. Alger also was a member of the staff of Fairview Hospital, Minneapolis.

He is survived by his wife, Isabel, and a son, Whitney, Monroe, Louisiana.

PETER BOYSEN

Dr. Peter Boysen, a physician at Pelican Rapids, Minnesota, for many years, died January 14, 1957. He was eighty years old.

Born in Denmark in 1876, Dr. Boysen received his medical education at the University of Pennsylvania and interned at Kensington Hospital in Philadelphia. He took postgraduate work at the University of Minnesota and began practicing medicine in Pelican Rapids in 1912. He served as president of the board of education for several years and was a member of the Park Region District and County Medical Society, the Minnesota State Medical Association and the American Medical Association. He had also served as Pelican Rapids health officer.

CARL N. HARRIS

Dr. Carl N. Harris, chief of staff of the Adams Clinic in Hibbing, Minnesota, died February 10, 1957. He was sixty-nine years old.

Born in Assumption, Illinois, Dr. Harris received his medical education at Rush Medical College, Chicago, and interned at Ancker Hospital, St. Paul. He joined the Adams Hospital staff in Nashwauk, Minnesota, in 1917, but left later that year to take postgraduate work at Bellevue Hospital, New York City.

He served in France as a captain in the U. S. Army Medical Corps during World War I.

Dr. Harris practiced medicine in Wilmot, South Dakota, from 1919 to 1923, and rejoined the Adams staff in Nashwauk in 1923. He opened clinic offices in Chisholm in 1927 and moved to Hibbing in 1928. He became chief of staff of the Adams Clinic in 1952 when Dr. Bertram Adams retired.

A former chief of staff of Hibbing General Hospital, Dr. Harris was also a past president of the Range Medical Society, a member of the Minnesota State Medical Association and the American Medical Association.

He served as Hibbing village health officer during a period in which the local health department received national recognition. He was also a past president of the Minnesota State Sanitary Association.

Dr. Harris' civic interests were many and varied. He was a 32nd degree Mason, a past master of the Iron Range Lodge of Perfection and a member of the Shrine. A member of the Kiwanis Club, he served as its president at one time. He also served as a commander of the American Legion, and was a member of the Veterans of Foreign Wars and the Chamber of Commerce. He belonged to the First Presbyterian Church.

Dr. Harris is survived by his widow, Doris; two daughters, Mrs. Andrew (Margaret) McNitt, Pittsburgh, and Mrs. Duke (Shirley) Durfee, Washington, Illinois; a son, Carl M., a student at Rochester Medical School, Rochester, New York; a sister, Miss Rose Harris, Chicago; and two grandchildren.

ZACHARIAH EUGENE HOUSE

Dr. Zachariah E. House, a resident of Cass Lake, Minnesota, for thirty-five years, died at his home in Burbank, California, January 14, 1957. He was eighty years old.

Born in Baltimore, Maryland, in August, 1876, Dr. House received his medical education at George Washington University, Washington, D. C. He also received a degree in dentistry.

In 1910 Dr. House moved to Cass Lake, where he was employed as a physician for the Indian Bureau. He was twice mayor of the town as well as president of the board of education, president of the local golf club, the Booster Club and an active participant in church and other civic activities.

A major in the medical reserve of the United States Army, Dr. House was a member of the Upper Mississippi Medical Society, the Minnesota State Medical Association and the American Medical Association.

He is survived by his widow, Minnie; three daughters: Peggy, Burbank, California; Mrs. Bertram Donaldson, Jacksonville, Florida, and Mrs. Harold Lee, Grand Rapids, Minnesota; one son, James, Burbank, and a number of grandchildren and great-grandchildren.

Much has been written about the eradication of tuberculosis, and the fall in mortality and morbidity figures has given hope that it may be realized in the future. But to accomplish this desirable state of affairs, it is essential to find and control the chronic infectious cases. We cannot hope to get rid of tuberculosis until we do this for they are like the red-hot embers that remain after the main fires of a bonfire have died down and can set alight any nearby combustible material.—F. R. G. HEAF, M.D., *J. Royal Inst. Pub. Health and Hygiene*, Nov., 1955.

TRUE ANTICHOLINERGIC ACTION

Pro-Banthine® Inhibits Excess Parasympathetic Stimuli in Peptic Ulcer

Medical literature now contains more than 500 references to the beneficial role of Pro-Banthine Bromide (brand of propantheline bromide) and Banthine® Bromide (brand of methantheline bromide) as evidenced by a marked healing response of peptic ulcers. Rapid symptomatic improvement, particularly with reference to pain relief, is followed by roentgenographic demonstration of crater filling.

The therapeutic action of Pro-Banthine in

decreasing hypermotility and hyperacidity, together with the remarkable early subjective benefit, is a desired approach in the management of ulcers.

The initial suggested dosage is one tablet, 15 mg., with meals and two tablets at bedtime. An increased dosage may be necessary for severe manifestations and then two or more tablets four times a day may be indicated. G. D. Searle & Co., Chicago 80, Illinois, Research in the Service of Medicine.

SEARLE

THE MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

230 Lowry Medical Arts Building, Saint Paul 1, Minnesota

F. H. Magney, M.D., Secretary

CHASKA, MINNESOTA, MAN SENTENCED IN MINNEAPOLIS FOR BASIC SCIENCE VIOLATION

Re: State of Minnesota vs. Ralph E. Dixon

On January 7, 1957, Ralph E. Dixon, 49, Route No. 2, Chaska, Minnesota, was sentenced by the Hon. Theodore B. Knudson, Judge of the District Court of Hennepin County, to a term of one year in the Minneapolis Workhouse on a charge of practicing healing without a basic science certificate. Dixon had previously entered a plea of guilty to an information charging him with that offense on November 2, 1956. Judge Knudson ordered the execution of the sentence stayed, however, and placed the defendant on probation for a period of one year.

Dixon, who was selling vibrators manufactured by the Niagara Manufacturing and Distributing Corporation, Adamsville, Pennsylvania and recommending their use in the treatment of various diseases such as arthritis and bursitis, was arrested after an investigation into his activities had been conducted by the Federal Food and Drug Administration, the Minneapolis Police Department and the Minnesota State Board of Medical Examiners. The defendant was selling the vibrators, which were called the "thermo-cyclopad" and the "hand unit" in a Minneapolis department store. However, he also went to a prospective customer's home in order to demonstrate the machines. While Dixon was recommending the use of a "thermo-cyclopad" in the home of an agent of the Federal Food and Drug Administration for treating a stiff back, his sales talk was being recorded without his knowledge. The machine was then purchased for the sum of \$169.00. Subsequently, on October 24, 1956, a criminal complaint charging Dixon with violating the basic science law was signed by a representative of the Minnesota State Board of Medical Examiners and the defendant was taken into custody.

In a signed statement the defendant admitted that he had been recommending and selling these machines for use in the treatment of arthritis, and that he had stated that poor circulation and injuries frequently caused arthritis. He further admitted that he had represented that by the daily use of the "thermo-cyclopad," the calcium deposits in the body would be broken up and eventually the joints would be usable. The smaller machine, called the "hand unit," sold for the sum of \$74.50. Dixon, who holds no licence to practice any form of healing in the State of Minnesota, has no training in medicine and his experience has been mostly in sales work.

LICENSE OF SAINT PAUL PHYSICIAN REVOKED

Re: Revocation of the License of Roy C. Heron, M.D.

Following a hearing held on November 9, 1956, the Minnesota State Board of Medical Examiners revoked the medical license of Roy C. Heron, M.D., seventy-one, who maintained an office for the practice of medicine at 719 Hamline Avenue North, Saint Paul, Minnesota. Dr. Heron, a former deputy coroner of Ramsey County, had been charged in a citation issued by the Board on August 21, 1956, with aiding and abetting a criminal abortion upon a thirty-two-year-old Saint Paul divorcee. He was also charged with failing to keep case and history records on the various patients that he had attended professionally during the past ten years.

Although the citation had been previously served upon

Dr. Heron, he did not appear at the hearing to give evidence in his own behalf. However, evidence was submitted to the Board that Dr. Heron had packed the patient with gauze in April, 1956, in order to terminate her pregnancy and that he was paid the sum of \$200.00. When the patient later became ill and was hospitalized in a Saint Paul hospital, the matter came to the attention of the Minnesota State Board of Medical Examiners.

Dr. Heron, who was born in New Brunswick, Canada, in 1885, attended the Medical School of Hamline University in Saint Paul, where he was granted an M.D. degree in 1908. He was licensed to practice medicine in Minnesota in the same year.

ST. PAUL DENTIST SENTENCED TO EIGHT-YEAR PRISON TERM ON ABORTION CHARGE

Re: State of Minnesota vs. Earl S. Weber

On January 17, 1957, Earl S. Weber, sixty-one years of age, was sentenced by the Hon. Royden S. Dane, Judge of the District Court of Ramsey County, to serve a term of not to exceed eight years in the State Prison at Stillwater, Minnesota, following a plea of guilty by Weber on January 7, 1957, to an information charging him with the crime of abortion. The defendant had also entered a plea of guilty to a charge of having a prior conviction for a felony.

Weber, formerly a licensed dentist, who maintained an office at 311 Newton Building, St. Paul, was arrested on December 10, 1956, when it was learned that a thirty-one-year-old married woman who was suffering from the after-effects of an abortion had been hospitalized on the previous day at Ancker Hospital in St. Paul. The defendant in a signed statement admitted that he had agreed to perform the abortion when the woman first came to his office in the middle of November, 1956, but since she only paid him \$50.00 at that time he waited until November 30, 1956, when he was paid an additional \$50.00, at which time he performed the illegal operation by the use of a curette. Weber also admitted that he had issued a prescription for twelve tablets of penicillin for the patient.

Weber has a previous conviction for a felony, having entered a plea of guilty on January 27, 1949, in the District Court of Ramsey County to an information charging him with the crime of abortion. For that offense Weber was sentenced to a term of not to exceed four years in the State Prison, but the sentence was stayed and the defendant was placed on probation for four years. Weber's probationary period, however, was terminated on May 10, 1951, and within three months he became involved in another difficulty which resulted in his arrest. On August 10, 1951, Weber was sentenced by the Hon. Arthur A. Stewart, Judge of the District Court of Ramsey County, to pay a fine of \$500.00 or serve ninety days in the Ramsey County Jail following his plea of guilty to an information charging him with the crime of practicing healing without a basic science certificate, which is a gross misdemeanor. Weber paid the fine.

The investigation in that case disclosed that a twenty-five-year-old married woman had gone to Weber for the purpose of having an abortion performed. How-

about the

PROFESSIONAL CREDIT PROTECTIVE BUREAU

The Professional Credit Protective Bureau has proved very beneficial to many professional people who have adopted this excellent credit control and collection service.

We urge you to make use of this service since it will be of great benefit in recovering long delinquent accounts and in eliminating, through proper control measures, the accumulation of slow and bad accounts.

Professional Credit Protective Bureau

701 Metropolitan Bldg., Minneapolis 1, Minn.

YES, I would like to give the PROFESSIONAL CREDIT PROTECTIVE BUREAU a trial. Please ask one of their representatives to call on me without obligation to explain the plan in detail.

NAME

ADDRESS

General Interest

At the annual meeting of the staff of St. Luke's Hospital, Duluth, on January 17, **Dr. Corrin H. Hodgson** of the Mayo Clinic was the principal speaker, presenting a medical travelogue entitled "Tsetse, Juju, and Tom-Toms," illustrated with motion pictures taken on a recent trip to Africa. **Dr. P. N. Bray**, obstetrician, became chief of staff of St. Luke's at that time, succeeding **Dr. Arden L. Abraham**.

* * *

Dr. Jack V. Wallinga, Minneapolis, has recently been appointed child psychiatry consultant to the Division of Child Welfare, of the Minnesota State Department of Public Welfare.

* * *

After two years' service in the U. S. Army Medical Corps at Fort Lee, Virginia, **Dr. J. C. Von Drasek** has returned to Mankato and reopened the practice which he began there in 1948.

* * *

The Detroit Lakes Clinic on February 1 moved into a new and modern building of thirty rooms on two levels. Members of the clinic who will enjoy the new facilities are **Drs. L. H. Rutledge, John B. Rutledge, C. W. Moberg, M. E. Odland, and E. W. Lorentzen**.

* * *

In late January **Dr. Malcolm A. McCannel**, Minneapolis, left for a two months' stay in Pakistan where he will serve on the staff of a free eye surgery clinic in Shikarpur. The forty-year old clinic, financed by the Church of England, specializes in the treatment and removal of cataracts.

* * *

Dr. Burton C. Sandberg, who has been associated with the East Range Clinic at Aurora for the past six months, left January 3 to join the U. S. Air Force. **Dr. Sandberg** is the first person born and raised in Aurora to enter the medical profession.

* * *

Four Mayo Clinic surgeons participated in the sectional meeting of the American College of Surgeons in New Orleans, February 4 to 7. **Dr. John L. Emmett** presented the diagnosis and treatment of adrenal tumors; **Dr. F. Henry Ellis** participated in the ophthalmology program; **Dr. James T. Priestly** talked on carcinoma of the stomach, and **Dr. John M. Waugh** outlined surgical procedures in treating peptic ulcers. In addition, **Dr. Priestly** was the principal speaker at a dinner meeting, February 3, preceding the sectional meeting.

* * *

At a recent meeting of the advisory board of St. Mary's Hospital, Minneapolis, **Dr. John P. Kelly** was elected chief of staff to succeed **Dr. James E. Trow**. **Dr. C. N. Borman** was elected vice chief of staff, and **Dr. N. J. Musty** was selected to serve as secretary-treasurer. Other members of the hospital advisory board include **Dr. Trow, Dr. Richard Neary and Dr. Robert E. Priest**.

Thirty members of the Rochester Dietetic Association heard an address on January 10 by **Dr. H. M. Odel** on "Acute Renal Insufficiency and Diet Relationship."

* * *

Dr. J. Earl Estes, of the section on vascular diseases of the Mayo Clinic, participated in a gerontologic symposium in Cincinnati, Ohio, in mid-January, presenting a paper on "Venous Disorders in Older People." In the same symposium, **Dr. Ancel Keys** of the University of Minnesota talked on "Calories and Cholesterol."

* * *

To point up the annual Heart Fund Campaign in Minnesota, the *Minneapolis Star* on January 28 carried a feature story on **Dr. Victor Lorber** of the University of Minnesota, a career investigator for the American Heart Association. He is one of three heart research investigators in the United States, and the AHA is the only group in the country underwriting scientists on such a lifetime basis. **Dr. Lorber's** work is fundamental research, in that he is trying to learn what makes the heart function.

* * *

Dr. George D. Haggard, Minneapolis, celebrated his 100th birthday at his home on January 18, 1957. Until the time of his retirement five years ago, **Dr. Haggard** was the oldest practicing physician in Minnesota.

* * *

Staff officers of St. Barnabas Hospital, Minneapolis, elected recently are: Chief of staff, **Dr. William T. Walsh**; vice chief, **Dr. Edgar A. Webb**; secretary-treasurer, **Dr. John T. Moehn**; chief of medicine, **Dr. John W. Johnson**; chief of surgery, **Dr. W. G. Schaefer**; chief of surgical specialties, **Dr. M. J. Stewart**; chief of pediatrics, **Dr. L. F. Erickson**; chief of obstetrics and gynecology, **Dr. M. T. Mitchell**; and head of the intern committee, **Dr. N. H. Lufkin**.

* * *

Dr. William R. Blomberg, who has previously built a clinic at Princeton, is building a new clinic at Snelling Avenue and Highway 36, to serve the community of Roseville. March 1 was set as the opening date for this new building which will accommodate three doctors and have laboratory and surgery facilities for emergency and accident cases.

* * *

The Minnesota Education Association recently presented its Distinguished Service School Board Award for 1956-57 to **Dr. Edward Q. Ertl** of Ellendale. In addition to his medical practice, **Dr. Ertl** has devoted himself to the cause of education in his community and the state for many years, and has served on the Ellendale board of education for thirty-six years.

* * *

A head-on collision on February 8 took the life of **Mrs. Cristjana Biering**, whose husband, a native of

(Continued on Page A-38)

ACHROCIDIN is indicated for prompt control of undifferentiated upper respiratory infections in the presence of questionable middle ear, pulmonary, nephritic, or rheumatic signs; during respiratory epidemics; when bacterial complications are observed or expected from the patient's history.

Early potent therapy is provided against such threatening complications as sinusitis, adenitis, otitis, pneumonitis, lung abscess, nephritis, or rheumatic states.

Included in this versatile formula are recommended components for rapid relief of debilitating and annoying cold symptoms.

Adult dosage for ACHROCIDIN Tablets and new, caffeine-free ACHROCIDIN Syrup is two tablets or teaspoonfuls of syrup three or four times daily. Dosage for children according to weight and age.

Available on prescription only

reduce your lubricating
jelly costs . . .

use **SURGEL** liquid

AN
ULMER
PRODUCT

Surgel Liquid cuts costs of lubricating jelly materially. No waste often encountered with tube preparations occurs. Every drop can be used. Free-flowing, esthetic in appearance, Surgel Liquid will not clog the dispenser tip. And a very small amount lubricates a large area.

Surgel Liquid is sterile, too. Each batch is autoclaved. And a special "built-in" disinfectant wards off contamination.

A true "money-saver," Surgel Liquid is the choice in many hospitals, clinics and physicians' offices. Write for your trial supply. . . . MM-357b.

Supplied in pints with special dispenser; also gallons.

Iceland, is a medical fellow in pediatrics at University Hospitals, Minnesota. The Association extends its sympathy to Dr. Biering.

* * *

Dr. Merrill Chesler was the principal speaker at a meeting of the Minnesota Association of Plaintiffs Attorneys held at the Radisson Hotel, Minneapolis, November 30, 1956. His subject was "Reconstructive Surgery Following Trauma."

* * *

The annual meeting of the officers and board of members of the Mayo Association was held in Rochester on February 6, at which time all officers of the organization were re-elected. Medical members of the organization are: Dr. C. W. Mayo, chairman of the board of members; Dr. Waltman Walters, vice chairman; Dr. Samuel F. Haines, vice chairman; Drs. L. M. Randall and James T. Priestley, board members. Following luncheon, Dr. Frank J. Heck, chairman of two sections of medicine in the Clinic, spoke on "Current Developments in Medical Insurance," and Dr. Howard P. Rome, head of the Section of Psychiatry, outlined "The Place of Psychiatry in Modern Medicine."

* * *

Medical students submitting papers for the Schering Award, an annual competition among U. S. and Canadian medical students sponsored by the Schering Corporation, are showing a clear preference for the topic, "Recent Advances in the Biochemical Aspects and Treatment of Mental Disease." The papers dealing with this subject are almost double those submitted on cardiology and eye disorders, the other two subjects for the 1957 competition. The deadline for submission of manuscripts is June 30, 1957. The first prize in each of the three categories is \$1,000, and the second prize is \$500. Professionally useful gifts will be awarded for other outstanding papers. The contest is open to all medical students in the United States and Canada. Information may be obtained from the Schering Award Committee, 60 Orange Street, Bloomfield, New Jersey.

* * *

Dr. Edward Henderson, member of a section of orthopedic surgery at the Mayo Clinic, Rochester, and instructor in orthopedic surgery in the Mayo Foundation, Graduate School, University of Minnesota, has been awarded an exchange fellowship sponsored jointly by the American Orthopedic Association and the British Orthopaedic Association. One of four American and one Canadian orthopedic surgeons to be thus honored this year, Dr. Henderson will go to the British Isles in mid-April and spend seven weeks touring orthopedic centers in London, Oxford, Cambridge, Edinburgh, Glasgow and other cities.

* * *

As part of a symposium on "Living with Education," presented by the Women's College Board, composed of the alumnae clubs of twenty-nine member colleges, Dr. Adelaide M. Johnson, consulting psychiatrist and clinical professor of psychiatry at the University of Min-

nesota, spoke on "Education of a Woman to Meet Challenges and Conflicts" in Chicago, February 9.

* * *

The American Academy of Orthopedic Surgeons on January 28 awarded Dr. Leonard F. Peltier the Kappa Delta Award for research in orthopedic surgery. This annual award carries with it a prize of \$1,000. The research for this award was completed prior to Dr. Peltier's leaving for Kansas City, Kansas, where he is now Professor of Surgery and Head of the Section of Orthopedic Surgery at the University of Kansas Medical Center.

* * *

Dr. Edward A. Pasck, who has recently completed his residency in ophthalmology at Minneapolis General Hospital, has opened an office in Faribault.

* * *

Four Mayo Clinic staff members will participate in a series of "flying symposia" in the Far Pacific in April, under the sponsorship of the Bureau of Medicine and Surgery of the U. S. Navy. The four men—Drs. Winchel McK. Craig, Waltman Walters, John S. Lundy and James Eckman—will be part of a group of civilian specialists from medical centers in Chicago, Cleveland, St. Louis and Milwaukee who will take part in symposia presented at naval hospitals in Japan, the Marianas Islands, Guam, and at Tripler General Hospital, maintained by the Army, in Honolulu. Dr. Craig and Dr. Walters, who hold the grade of rear admiral in the U. S. Naval Reserve, will be assigned to active Naval duty for the duration of the trip; Drs. Lundy and Eckman will be consultants to the Bureau of Medicine and Surgery of the Navy during the period.

* * *

Dr. Leroy E. Burney, Surgeon General of the U. S. Public Health Service, has announced the recent appointment of Dr. Jerome T. Syverton, Minneapolis, to the National Advisory Allergy and Infectious Diseases Council. Dr. Syverton is head of the department of bacteriology and immunology at the University of Minnesota. As a council member, Dr. Syverton will assist in recommending and advising with respect to the grant activities of the National Institute of Allergy and Infectious Diseases, Bethesda, Maryland, which is one of seven institutes conducting research for the Public Health Service.

* * *

A Minnesota-born and trained physician, Dr. Thomas G. Petrick, has been named Pathologist and Director of the Laboratory at Good Samaritan Hospital in New York City. Dr. Petrick received his medical education at the University of Minnesota Medical School, and is a native of Eveleth, where his mother still resides.

* * *

On January 29, Dr. Otto W. Scholpp of Hutchinson enjoyed a combined celebration—his seventy-eighth birthday and his fiftieth anniversary as a physician. Dr. Scholpp has practiced in Hutchinson for forty-eight years, coming to that vicinity from Duluth.

* * *

Dr. Carl Simison, Barnesville, has succeeded Dr. J. F.

New Book Announcement by YEAR BOOK PUBLISHERS

DAVIS' RADICULAR SYNDROMES with Emphasis on Chest Pain Simulating Coronary Disease

Just Published!—The first manual of its kind dealing with cervical and thoracic spinal root syndromes from the internist's and general practitioner's point of view. Its primary aim is to aid the diagnostician in definitely determining the significance of chest pain—Is it coronary disease or is it of root origin? In addition to the detailed coverage of chest pain, Dr. Davis goes fully into discussion of chest wall tenderness, respiratory distress, shoulder girdle symptoms, headache, and vertigo of cervical origin. Greatest stress is properly placed on clarifying diagnostic problems. Treatment is also given concisely and simply to make for a thoroughly complete consideration.

By David Davis, M.D., Beth Israel and Faulkner Hospitals, Boston. 270 pages; illustrated. \$6.50

STEEGMANN'S EXAMINATION OF THE NERVOUS SYSTEM

New!—This practical, pocket-size manual sets forth clearly and simply the practical essentials of neurologic history-taking and the basic techniques of the neurologic examination. Written especially for those who recognize the need for refresher training in this important but too often overlooked aspect of medical practice. Accordingly, special pains have been taken to mark the specific paths of procedure, define the line of objective interrogation and sharply focus the powers of visual observation which, when applied in unison, lead to definitive diagnoses.

By A. Theodore Steegmann, M.D., Professor of Medicine (Neurology), University of Kansas School of Medicine. 164 pages; illustrated. \$3.75

Schneider of Moorhead as president of the medical staff at St. Ansgar Hospital, Moorhead. Dr. Arthur Burt, Fargo, was chosen vice president, and Dr. James W. Duncan, Moorhead, was named secretary-treasurer. In addition to Drs. Simison, Duncan, Burt, and Schneider, Drs. R. E. Kulland, West Fargo, and B. T. Bottolfson, Moorhead, will serve on the executive committee.

* * *

A physician and a psychiatrist have recently joined the staff of the Fergus Falls State Hospital. Dr. Ruta Jauniskis, a native of Lithuania, who has served as resident physician at Mounds Park Hospital, St. Paul, took over her duties as physician at the state institution on January 3. Dr. Richard Ahrens, who was associated with the Fergus Falls Hospital from 1938 to 1940, returned January 15 to take over his new duties as psychiatrist.

* * *

In a report prepared for the annual meeting of the American Society of Surgery of the Hand, Drs. Paul R. Lipscomb, Edward D. Henderson, and Earl C. Elkins of the Mayo Clinic described tendon transfer operations which have restored the use of hands and fingers resulting from paralysis from broken necks, describing nine such operations performed at the Clinic in the last two years.

* * *

Dr. E. H. Ryncarson of the Mayo Clinic spoke on family health at the annual banquet of the Minnesota Council of Painting and Decorating Contractors in Rochester in late January.

* * *

Dr. Irving C. Bernstein addressed a meeting of the North Dakota branch of the American Academy of General Practice in Fargo, December 8, 1956. His subject was "The Etiology and Management of Pruritus Vulvae."

* * *

Dr. John S. Lundy, founder of the Section of Anesthesiology at the Mayo Clinic and professor of anesthesiology in the Mayo Foundation Graduate School, University of Minnesota, is the subject of a two-page tribute, entitled "We Salute . . . John Silas Lundy, M.D., in the January-February issue of *Analgesia and Anesthesia*, official organ of the International Anesthesia Research Society.

Dr. Lundy introduced pentothal sodium for clinical practice in 1934, and was the first to use radioactive pentothal. He established the first blood bank in 1935, and the first postanesthesia recovery room in 1942. He organized the Anatomy Department of the Mayo Clinic and Mayo Foundation in 1927, and supervised it until 1947. He has written a textbook entitled "Clinical Anesthesia" and an almost endless number of papers, book reviews, editorials and abstracts. He established *Anesthesia Abstracts*, and has been editor of the Section on Pain of *The Journal-Lancet* since 1952.

* * *

The Upper Mississippi Medical Society met on January 19, 1957, in Brainerd, Minnesota. After the business session.

* * *

Dr. William E. Proffitt, Minneapolis, was photographed by members of the Minnesota press as he administered a Salk vaccine shot to Governor and Mrs. Orville Freeman in January.

* * *

Dr. Leo G. Rigler, Minneapolis, spoke on "The Detection of Disease in its Incipency" at the 19th annual Clinic Day of Mount Carmel Mercy Hospital in Detroit, Mich., January 30.

* * *

Dr. H. Mead Cavert has been named assistant dean of the University of Minnesota medical school to succeed Dr. William F. Maloney who resigned to become dean of the College of Virginia Medical School.

* * *

Dr. John H. Moe has been appointed clinical professor and director, division of orthopedic surgery, University of Minnesota medical school. He was formerly assistant clinical professor of surgery.

* * *

Dr. P. J. Parker and Dr. J. E. Nord, Hallock, plan to set up practices in Staples, Minnesota, this spring.

* * *

Dr. Jack R. Pierce, a staff member of the Lenont Peterson Clinic in Virginia, has left with his family for Pikesville, Kentucky, where he has accepted a position with the United Mine Workers' Hospital.

* * *

Dr. Hershel Cope has completed a residency in obstetrics and gynecology at St. Joseph's Hospital, St. Paul, and has returned to his post with the Lenont Peterson Clinic, Virginia.

* * *

Physicians and attorneys discussed mutual problems at a meeting in Grand Rapids, Minnesota, recently. Four physicians and four attorneys formed a panel to discuss these problems. The physicians were Dr. M. J. Schirber, Dr. John Evensta, Dr. O. C. Braun and Dr. M. J. McKenna, all of Grand Rapids.

* * *

Dr. C. B. McKaig, Pine Island, recently celebrated the start of his 51st year as a physician.

* * *

Dr. Norman W. Hoover, formerly associated with the East Range Clinic, Virginia, has begun a residency in orthopedic surgery at the Mayo Clinic.

* * *

Dr. Myron J. Woltjen, Rushford, has entered military service; in his absence Dr. Hilmar R. Schmidt, formerly of Winona, and Dr. Warren W. Haesley, Winona, will be located in Rushford. Dr. Schmidt has moved to Rushford and Dr. Haesley will hold office hours there five mornings each week.

* * *

Dr. J. L. Mills, is observing his 35th year of practicing medicine in Winnebago. He and his present partner, Dr. D. E. Halverson, are moving into a new office building this month.

Gordon R. Kanman, M.D., and Charles Murnane, L.B., spoke at a joint meeting of the Tri-County Medical Society and the local attorneys at Willmar on Thursday, February 14. Their subject was "Medical-legal Relationships."

* * *

Dr. Nicholas Mensheha, Forest Lake, appeared on the television quiz show "Strike It Rich" to raise funds for the thirty-bed hospital planned for his community. Dr. Mensheha, a native of Kiev, fled from the Russian Ukraine with his infant daughter after the death of his wife.

* * *

Dr. Fred A. Rice has been elected chief-of-staff of Doctors' Memorial Hospital, Minneapolis. He succeeds Dr. Alan Blake. Other officers named include Dr. Lewis O. Zahrendt, assistant chief of staff, and Dr. Malcolm McCampbell, secretary-treasurer.

* * *

Dr. Dale Cameron, medical director, Minnesota Department of Public Welfare, spoke on mental illness at the recent Industrial Relations Center Labor Conference sponsored by the University of Minnesota.

* * *

Dr. William C. Menninger, general secretary of the Menninger Foundation, Topeka, Kan., addressed the annual dinner of the Minnesota Association for Mental Health, January 30. He also spoke before both houses of the Minnesota legislature.

* * *

Dr. Paul Dudley White, noted heart specialist, spoke at the kick-off breakfast of the Heart Fund campaign in Minneapolis, February 4.

* * *

Dr. A. F. Risser, Stewartville, has been elected chief of staff of the Olmsted Community Hospital, Rochester. He succeeds Dr. John E. Verby, Rochester. Other new officers are Dr. N. J. O'Keefe, Spring Valley, vice-president, and Dr. John R. Watson, Rochester, secretary-treasurer.

* * *

Drs. Mark Coventry, Lyle Weed, Robert Kierland and Paul R. Lipscomb, Rochester, spoke at a recent meeting in Chicago. This meeting was held to consider medical problems affecting the hands.

* * *

Dr. Lawrence D. Amick, who has completed a three-year fellowship in physical medicine in the Mayo Foundation, Graduate School, University of Minnesota, at Rochester, has been awarded a research fellowship from the National Foundation for Infantile Paralysis, of New York. The fellowship will allow Dr. Amick to continue his graduate work in clinical electromyography in London, England. He had done extensive graduate work in this field while he was a fellow of the Mayo Foundation.

* * *

Drs. E. H. Soule, M. B. Coventry, E. D. Henderson, P. R. Lipscomb, R. K. Ghormley, J. M. Janes, P. J. Kelly, H. H. Young and W. H. Bickel took part in the recent meeting of the American Academy of Orthopedic Surgery held in Chicago. All are from Rochester.

Dr. Victor Johnson, Rochester, director of the Mayo Foundation for Medical Education and Research, presided over a session of the 53rd Annual Congress on Medical Education and Licensure held in Chicago, February 9-11.

Variations and loss of sensitivity to tuberculin have been observed in the course of some diseases. These changes are usually of a transitory nature, and tuberculin hypersensitivity returns with the improvement or recovery of the patient. The tuberculin reaction which may be slight or absent in those suffering from far advanced tuberculosis or tuberculous meningitis may return in those whose condition improves under antimicrobial treatment.—JOSEPH D. ARONSON, HELEN C. TAYLOR, DANIEL L. KIRK, *Am. Rev. Tuberc.*, July, 1956.

MINNESOTA BLUE CROSS-BLUE SHIELD

Both the amount Minnesota Blue Shield paid doctors for care of subscribers during 1956, and the number of physicians' services involved in the total amount paid were over 20 per cent greater than during 1955. This 10 per cent increase in payment and services cannot be accounted for solely by the increased number of subscribers enrolled which amounted to an increase of 13 per cent of the year of 1956.

Blue Shield provided benefits of \$6,919,348 during 1956 for physicians' services to participant subscribers. This figure is equal to average monthly payments of \$576,612, and is \$1,183,182 greater than the total amount paid by Blue Shield for physicians' services to subscribers during 1955, which amount was \$5,736,166.

The number of physicians' services to subscribers for which Blue Shield provided benefits during 1956 was 150,600, exceeding by more than 50,000, or approximately 25 per cent, the number of doctors' services for which Blue Shield provided payments during 1955.

The increase in total Blue Shield payments during 1956 over 1955, and the increased number of physicians' services for which Blue Shield provided benefits reflect not only the increased number of participant subscribers, but also greater utilization and improvements of Blue Shield coverage.

Addressing the annual members meeting of Minnesota Blue Cross held Thursday, February 21, 1957, in St. Paul, Arthur M. Calvin, president, announced that of a total of \$25,000,000 received from subscribers in 1956, hospital benefits paid to subscribers totaled \$23,501,546. This was the highest amount paid to Minnesota Blue Cross subscribers in the history of the organization. The \$23,501,546 figure represents 93.1 per cent of total subscriber income for the year 1956.

Commenting on the statement of conditions, Calvin pointed out that Blue Cross also had the lowest operating costs of the organization's history . . . 5.2 per cent.

Calvin explained that during the twenty-three years of the existence of Minnesota Blue Cross over \$146,000,000 has been paid to members in the form of hospital benefits. Commenting on this total figure, Calvin pointed out that in addition to the increased number of persons using hospital facilities compared with past years, people are also faced with the problem of increased hospital costs. "However, none of us would care to go back to the old days when many of today's scientific medical-surgical techniques were unheard of," Calvin explained.

Calvin, who is also a governor of the newly created Blue Cross Association, announced to the members that Dr. Basil C. McLean had accepted the presidency of that organization. Dr. McLean resigned his position as New York Commissioner of Hospitals to accept the new post. The new Blue Cross Association was formed to service the needs of the nation-wide employer.

Commenting on the relationship of Blue Cross and the American Hospital Association, Calvin paid tribute to the officers and staff of that organization for their assistance in developing a cost basis for payment to hospitals by third party organizations; in government

relations at the national and local level, in endeavoring to provide health care to a greater number of people without imposing a compulsory national health system in the United States.

Calvin concluded by saying: "The philosophy of Blue Cross is as basically sound today as it was 23 years ago when seven hospitals initiated the program. The people of Minnesota are in need of the services of an organization such as Blue Cross today, as they were during the depression days."

Richard T. Crist, Vice President in charge of internal operations, told members that, during 1956, accident cases among Blue Cross members showed a marked increase. During 1956, Blue Cross benefits were provided for 30,069 accident cases, compared to 25,524 cases during the previous year. This increase represented approximately \$500,000 in hospital expenses over 1955.

Donald J. Condon, Vice President in charge of enrollment and public relations, announced that 1,106,134 participants are now enrolled in Blue Cross. This figure represented an eight per cent gain over 1955 . . . a record year.

ST. PAUL DENTIST SENTENCED TO PRISON TERM

(Continued from Page A-34)

ever, Weber denied that he intended to perform an abortion but admitted that he had made a vaginal examination of the patient, advised the patient she was pregnant and inserted "about twelve inches of gauze in her vagina." The defendant was paid \$50.00 by the patient for his services in that case. Weber, who was born in Louisiana on January 26, 1896, is a graduate of the Dental School of the University of Minnesota in 1921. On January 11, 1957, the Minnesota State Board of Dental Examiners revoked Weber's license to practice dentistry.

There is perhaps no infectious disease in which the etiologic role of environment is more important than in tuberculosis. There can of course be no tuberculosis without the tubercle bacillus, but aside from a part in determining the opportunities for contact between the sick and the healthy, environment has a continuing and vital influence upon the severity, course and fatality of the disease.—ALTON S. POPE, M.D., and JOHN E. GORDON, M.D., *Am. J. Med. Sciences*, September, 1955.

* * *

It is certain that there are millions of individuals in the United States today, possibly 50 million, who are infected with tubercle bacilli. ROBERT J. ANDERSON, M.D., *Pub. Health Rep.*, February, 1956.

Book Reviews

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED

SURGERY IN WORLD WAR II. Orthopedic Surgery in the European Theater of Operations. Colonel John Boyd Coates, Jr., MC., Editor-in-chief; Mather Cleveland, M.D., Editor for Orthopedic Surgery; Elizabeth M. McFetridge, M.A., Associate Editor. 397 pages. Illus. Price 4.00, cloth. Washington, D.C.: U. S. Printing Office, 1956.

SURGERY IN WORLD WAR II. Volume II. General Surgery. Colonel John Boyd Coates, Jr., MC., Editor-in-chief; Michael E. De Bakey, M.D., Editor for General Surgery; W. Philip Giddings, M.D., and Elizabeth M. McFetridge, M.A., Associate Editors. 417 pages. Illus. Price \$4.25, cloth. Washington, D. C.: U. S. Printing Office, 1955.

GENERAL UROLOGY. Donald R. Smith, M.D., Clinical Professor of Urology and Chairman of the Department of Urology, University of California School of Medicine, San Francisco. Consulting Urologist, San Francisco Hospital; Consulting Surgeon (Urology) Veterans Hospital, San Francisco; Chief of the Department of Urology, St. Luke's Hospital, San Francisco. 328 pages. Illus. Price \$4.50, paper cover. Los Altos, California: Lange Medical Publications, 1957.

CLINICAL ROENTGENOLOGY, VOLUME IV, THE DIGESTIVE TRACT, THE GALLBLADDER, LIVER AND PANCREAS, THE EXCRETORY TRACT. By Alfred A. DeLorimier, M.D., Radiologist St. Francis Memorial Hospital, San Francisco, California; Harry G. Moehring, M.D., Radiologist, Duluth Clinic, Duluth, Minnesota; and John R. Hannan, M.D., Radiologist, Cleveland, Ohio. Cloth bound, \$24.50, 676 pages, 1112 illustrations. Springfield, Illinois: Charles C Thomas, 1956.

In this volume the authors present the roentgen approach for study of the alimentary tract, and the genitourinary tract. The presentation is thorough and yet is concisely written. The authors attempt to integrate the x-ray manifestations with the clinical picture.

Each organ, condition or disease is considered separately and divided into the logical subdivisions of general considerations, roentgen manifestations, clinical correlation, laboratory corroboration, and differential considerations. The bibliographies are adequate. The physical characteristics of the book are exceptionally good. It is clearly printed and a double column form makes for easy reading. The roentgenogram reproductions are good.

Radiologists will find this volume of particular value, but it is a good reference for all clinicians.

Sulfonamide and Antibiotic Therapy —After Twenty Years

WESLEY W. SPINK, M.D.
Minneapolis, Minnesota

AFTER receiving my medical training elsewhere, I began my academic career at the University of Minnesota Medical School and Hospitals on August 1, 1937. I cite this personal note in introducing this subject because of the significance of the date. I had my clinical apprenticeship relative to the infectious diseases prior to the sulfonamide-antibiotic era, and I arrived at Minnesota with prontosil and sulfanilamide. For the last twenty years, all but one spent at Minnesota, I have had the opportunity with my colleagues of evaluating many drugs employed in the management and treatment of infectious diseases. Before plunging into a recital of the impact of these new forms of chemotherapy upon infectious diseases, I cannot resist referring to another personal aspect of my first days here at Minnesota. Late in the fall of 1939, Dr. E. T. Bell asked me if I would participate in a series of public lectures sponsored by the Minnesota Chapter of the Society of Sigma Xi, and suggested that I speak on chemotherapy. I took as my subject, "Sulfanilamide and Related Chemicals in the Treatment of Infectious Disease." On the night of February 2, 1940, I reviewed our clinical experience of two years at the University Hospitals with these new agents. I concluded my remarks by stating that we were working in a rapidly developing field. Sulfanilamide had been succeeded by sulfapyridine, and at that time we were engaged in studying a new compound, sulfathiazole! Incidentally, that lecture was published in the *Sigma Xi Quarterly*¹, and it was the germination of a subsequent monograph that I prepared on the subject².

From the Department of Medicine, University of Minnesota Hospitals and Medical School, Minneapolis.

Presented before the Minnesota Pathological Society, January 15, 1957.

Historical Highlights

Although Domagk possessed decisive experimental proof as early as 1932 that the red dye, prontosil, protected animals against lethal streptococcal disease, his report did not appear until 1935. But in the intervening three years there were rumblings in the German literature indicating that human streptococcal illness also responded favorably. Of the utmost significance in the development of this new form of chemotherapy were the observations of the French investigators, which revealed that the *in vivo* antibacterial action of prontosil was due to the liberation of para-amino-benzene-sulfonamide (sulfanilamide) by the host's tissues. From then on a rapid succession of sulfonamide compounds were studied and many adopted for use in human illness. The first report in America was by Long and Bliss³ in 1936, and at this time Dr. Chester Keefer and I started investigations on the use of prontosil and sulfanilamide in streptococcal and gonococcal infections.

Although the fundamental observations of Fleming⁴ on penicillin were published in 1929, it was not until 1941 that this antibiotic was administered parenterally to man. Just prior to the successful application of penicillin to diseases of man, Dubos⁵ announced his brilliantly conceived studies with tyrothricine. Unfortunately, the constituents of this antibiotic, gramicidin and tyrocidine, were too toxic to be administered systemically. The first recipient of penicillin at the University Hospitals was a seven-year-old girl, critically ill with acute staphylococcal bacteremia and osteomyelitis. The temperature was 105° F. and pulse 156. She was disoriented, and sixty-eight colonies of staphylococci per ml. of blood were present. The initial dose was given on June 11, 1942. The results were so dramatic, and the doses of penicillin,

all given intravenously, were so small, that the treatment is detailed as follows: 10,000 Oxford units every 4 hours x 4; 5000 units every 4 hours x 32; 2500 units every 4 hours x 20. The total dose was 252,500 units given over a period of fifteen days.

Waksman and his associates³ announced the isolation of streptomycin in 1944, and clinical trials with the "broad-spectrum" antibiotics occurred in 1948. Our initial experience with chlor-tetracycline (aureomycin) was in 1948, during a cooperative study on the therapy of brucellosis at the Mexico General Hospital in Mexico City.⁷ Chloramphenicol and the tetracycline drugs have been succeeded, but not displaced, by other antibiotics. There is no doubt that a highly competitive pharmaceutical industry will bring forth additional antibacterial agents in the future.

Accomplishments

Time does not permit a detailed survey of the remarkable advancements that have taken place in the management of infectious diseases during the past twenty years. Therefore, only a cursory inventory will be made of some of the accomplishments.

Streptococcal Disease.—Infections caused by Group A hemolytic streptococci have always been greatly feared, not only because of the suppurative complications, but also because of the late non-suppurative conditions, such as acute rheumatic fever and glomerulonephritis. It soon became apparent that prontosil and sulfanilamide were highly effective agents for hemolytic streptococcal infections. Otitis media, mastoiditis, sinusitis, meningitis, bacteremia, puerperal sepsis, erysipelas—all responded favorably to treatment. It is to be recalled, however, that within five years after the introduction of sulfanilamide and its derivatives, strains of hemolytic streptococci that were highly resistant to the sulfonamides were encountered with increasing frequency. At the time of this development the country was at war, and a major medical catastrophe would have occurred in our military personnel because of these resistant streptococci, if penicillin had not become available. Today, erysipelas is a medical curiosity in our hospitals. Streptococcal mastoiditis is a rarity, and fatal streptococcal septicemia is uncommon. It is generally believed that the incidence of rheumatic fever can be considerably reduced by the

prompt and proper prophylactic and therapeutic use of penicillin.

The most feared complication induced by the less invasive strains of streptococci, such as *Streptococcus viridans*, is subacute bacterial endocarditis. Prior to the advent of penicillin this disease was usually fatal, while today, at least 80 per cent of the patients recover after proper therapy.

Pneumococcal Disease.—The pursuit of satisfactory antipneumococcal agents was difficult and frustrating. Just prior to the sulfonamide era, type-specific antipneumococcal sera proved quite effective for lobar pneumonia. Although hemolytic streptococcal disease tumbled before sulfanilamide, this agent was not effective in pneumococcal pneumonia. But sulfapyridine and other sulfonamides proved to be highly acceptable, and serotherapy was discontinued. Pneumococci cause over 90 per cent of all bacterial pneumonias, and penicillin has reduced the mortality rate to such an extent that Gannon⁸ has stated, "Our residents and medical students now learn about the pathologic aspects of lobar pneumonia only from books, from the reminiscences of older clinicians and pathologists and from museum specimens." Even the complications of pneumococci pneumonia, such as empyema, are seen uncommonly.

Venereal Diseases.—Any physician who attended the genito-urinary clinic of a large municipal hospital before the arrival of the sulfonamides can appreciate the almost unbelievable impact that the sulfonamides and penicillin have had upon the incidence of gonorrhea. Fruitless, and at times harmful, washes and massages in the male have given away to the extremely effective drug, penicillin. According to Dr. H. G. Irvine of the Minnesota Department of Health, there were 3,873 reported cases of gonorrhea in Minnesota in 1935. Although the number of cases has been considerably reduced, and the complications have been largely eliminated, there were still 1,000 cases of gonorrhea reported in 1955. We are mindful that what happened with the streptococcus was also true of the gonococcus. After a few years, strains of sulfonamide-resistant gonococci appeared, which often rendered treatment ineffective. Fortunately, penicillin became available. Another exciting accomplishment has been the virtual disappearance of that most painful and

disabling complication of gonorrhea, gonococcal arthritis, from our hospital population today. The distressing gonococcal complication of infants, ophthalmia neonatorum, which often led to blindness, has been almost completely eradicated.

The sulfonamides proved to be ineffective in the control and management of syphilis, but penicillin therapy has accomplished essentially what has happened with gonococcal infections. According to Irvine there were 181 cases of primary and secondary syphilis reported for 1940 in Minnesota, whereas in 1955 there were only twenty-two cases. In addition, in 1940 there were 113 cases of congenital syphilis. During the years 1950-1955, inclusive, there were only six cases of congenital syphilis reported, and only three infected babies were born in Minnesota. The large number of cases of congenital syphilis reported in 1940 was partly due to the screening of individuals for Selective Service. Bell⁹ has commented upon the fact that congenital syphilis has virtually disappeared from the community.

Bacterial Meningitis.—Acute suppurative meningitis of bacterial origin has responded, often dramatically, to sulfonamide therapy since the earliest days. Hemolytic streptococcal meningitis was a common complication of otitis media, mastoiditis, and sinusitis, with a mortality rate approaching 90 per cent. Today, this form of meningitis is a rarity, and fatalities are extremely rare. I have not even seen a case of streptococcal meningitis within the past ten years. The terror of epidemic meningococcal meningitis has long subsided, and even with the sporadic case, early diagnosis and treatment result in prompt recovery. Even if an epidemic of meningococcal meningitis should threaten the security of a closed population, the danger can be eliminated overnight by administering sulfonamide to all the individuals. Although many effective antibiotics are now available, sulfadiazine is still the drug of choice for meningococcal meningitis. A biologic phenomenon of considerable interest is the fact that the gonococcus is very closely related to the meningococcus; and while strains of sulfonamide-resistant gonococci have appeared, similar resistant strains of meningococci have not posed a clinical problem. The most common form of bacterial meningitis in infancy and early childhood is that due to type B *Hemophilus influenzae*. Influenzal meningitis still occurs only too frequently, carrying

with it a mortality rate in the untreated cases of around 90 per cent, and even in those patients treated properly, serious brain damage may ensue. Although respiratory infections of pneumococcal origin respond very favorably to penicillin and to other antibiotics, and although no antibiotic-resistant pneumococci appear to have been isolated, pneumococcal meningitis still constitutes a very serious disease having a mortality rate in well-treated patients approximating 50 per cent in some clinics. This mortality rate of unusual proportions is due in part to the disease afflicting elderly patients with debilitating complications, to delay in starting therapy, and, in some instances, to discontinuing therapy too soon.

Typhoid, Brucellosis and Rickettsial Diseases.—As clinical entities, these diseases do not have much in common. But from a host-parasite viewpoint certain general features are related. Satisfactory therapy was lacking until chloramphenicol and the tetracycline drugs became available. It is significant that although these agents lead to rapid recovery in the vast majority of patients, the microorganisms can persist in the asymptomatic host for considerable periods of time, probably in an intracellular position. Typhoid fever is still a common disease in many parts of the world; a disease of improper sanitation, and even in the United States, a constant threat to human health. Chloramphenicol is the most effective agent available, having reduced considerably the incidence of complications and the mortality rate. Nevertheless, the advancement of efficient antibiotic therapy has not reduced the incidence of the carrier rate. In fact, adequate therapy for the carrier state is lacking. Chloramphenicol is less effective in other forms of salmonellosis. The therapy of brucellosis has long been the subject of investigation in our laboratory and clinics.¹⁰ Treatment with the tetracycline drugs has brightened the picture considerably in the management of human brucellosis, even though relapses and chronic disease can occur in some individuals.

Rickettsial infections represent disease in which classical intracellular parasitism appears, and in which dramatic clinical improvement occurs as a result of antibiotic therapy. During World War II, scrub typhus harried our military personnel in the South Pacific with no effective therapy available, and mortality rates approached 35 per cent in

some areas.¹¹ The tetracycline drugs and chloramphenicol now afford prompt and progressive improvement for scrub typhus.

Tuberculosis.—Before World War II, I used to inform medical students that malaria was the Number 1 infectious disease in the world, and I fortified my statement with a quotation from Burnet,¹² "If we take as our standard of importance the greatest harm to the greatest number, then there is no question that malaria is the most important of all infectious diseases." But with the introduction of effective chemoprophylaxis and chemotherapy, malaria has been relegated to a much less commanding position. Most authorities are agreed that following World War II, tuberculosis took over first position. Like typhoid, tuberculosis is a disease of filth, poverty and poor nutrition. But tremendous advancements in therapy have been induced by the introduction of streptomycin, para-aminosalicylic acid (PAS), and isoniazid. The hopelessness of miliary tuberculosis has been succeeded by dramatic recovery in the majority of properly treated patients. Even tuberculous meningitis can be effectively treated, if therapy is started early in the course of the illness.

Contemporary Problems

Drug Toxicity.—Shortly after the miraculous results of sulfanilamide therapy became apparent to the pharmaceutical industry in the United States, their competitive spirit was more than aroused, and a hurried search for new and related agents was made. Prior to 1938 there were no restrictions on new drugs introduced into interstate commerce. Sulfanilamide would have been a highly profitable drug for any pharmaceutical concern to have synthesized and patented. But it was an old compound, not protected by patent rights, and available to any organization for marketing. Since sulfanilamide was not soluble in the usual safe solvents, one pharmaceutical group decided to market the drug with diethylene glycol as an effective solvent *without carrying out any toxicity studies*. But diethylene glycol was highly toxic, and "Elixir Sulfanilamide" caused over 100 deaths. This resulted in the present Food, Drug and Cosmetic Act, which requires that all new groups must be proved safe for human use before being placed on the market. After 1938, many derivatives of sulfanilamide appeared, each having been care-

fully screened for toxicity and therapeutic activity. Even then only a small number became acceptable on a large scale, and even in the face of new safeguards, not without tragic results. Sulfapyridine, and particularly sulfathiazole, produced severe and fatal renal dysfunction. In addition, the sulfonamides all provoked fever, skin reactions, and in some instances, severe blood dyscrasias.

The same story of drug toxicity has been repeated with the antibiotics. Penicillin, still one of the best of all antibiotics, is not without its dangers. Hypersensitivity reactions induced by penicillin mimic serum reactions. Acute anaphylactic shock with death has been observed on enough occasions to cause any physician to hesitate before administering penicillin to any person, either parenterally or by mouth. The delayed serum sickness-like syndrome with fever, arthralgia, urticaria and toxemia can cause an incapacitating and prolonged illness. In our experience, about 2 per cent of all patients receiving penicillin by parenteral routes express some degree of reaction to the drug, but I have never witnessed a fatal reaction to penicillin at the University Hospitals. The broad-spectrum antibiotics also carry a threat to human health. Chloramphenicol has caused a severe and fatal depression of the bone marrow. The tetracycline drugs can induce a severe enterocolitis, but rarely is this fatal. Approximately 10 per cent of our patients have experienced undesirable gastrointestinal side effects from the tetracycline group.

What attitude should the clinician take toward these antibacterial agents that can produce side effects of varying degrees of severity? First of all, it has not been surprising to me that an agent or agents, altering cellular metabolism of microorganisms so unfavorably that death results, should not on occasion alter the metabolic activity of the host in an undesirable manner. The surprising thing to me is that human beings haven't suffered more ill effects, when one considers the potential dangers, and the tremendous amounts of drugs that have been administered. Furthermore, any drug that alters functional activity of the host, and all drugs probably possess this property, is potentially harmful. A single tablet of acetylsalicylic acid has produced fatal anaphylactic shock on occasion. There is no point in condemning the sulfonamides or antibiotics because they can provoke serious side effects. The attitude of the clinician should be one

of discrimination and caution, employing these antibacterial agents only when his experience dictates that there is a reasonable indication for doing so. As clinicians we should hammer away on the public that the indiscriminate use of any drug is harmful.

The indiscriminate use of potentially dangerous drugs reminds me of Snapper's¹³ story of Paracelsus and antimony. Paracelsus in the sixteenth century recommended antimony by mouth for leprosy, scabies, burns and wounds. But the drug was used without caution, which led to disastrous consequences. In 1566 the Medical Faculty of the University of Paris forbade its use, and in 1580 Heidelberg University required every graduate to take an oath that they would never administer antimony by mouth. However, careful use of antimony by certain discriminating physicians did benefit patients, and after 100 years Paris University rescinded its ban on antimony and recommended it as a useful drug. In a more modern area, antimony proved life-saving in the therapy of kala-azar.

The Appearance of Drug-Resistant Microorganisms.—If anyone, prior to the modern era of therapy, had reviewed carefully the early history of chemotherapy for infectious diseases, he would have anticipated that drug-resistance would have posed many problems with the sulfonamides and with the antibiotics. Ehrlich and his school¹⁴ cited experimental evidence as a background for this phenomenon half a century ago. And, as I have already pointed out, this is precisely what happened with the sulfonamides in the management of streptococcal and gonococcal infections. On the other hand, penicillin has been widely used for a dozen years in the treatment of these infections, and penicillin-resistant strains of Group A hemolytic streptococci and gonococci have not been encountered. This also applies to pneumococci. Penicillin is still highly effective in infections caused by these bacteria; in fact, it remains the drug of choice.

But the story of the appearance of antibiotic-resistant strains of staphylococci has been a very discouraging one. Since our experience at the University Hospitals and at the Minneapolis General Hospital reflects that of many other clinics in this and other countries, some of the highlights of this problem as it has concerned us are given. Fortunately, we have carried out investigations on the

management of staphylococcal sepsis ever since the sulfonamides were first introduced, which has permitted a long-range study of the problem. Before penicillin became available in 1942 drug therapy was of little benefit in severe staphylococcal disease, with the possible exception of sulfathiazole. We had collected sixty-seven strains of coagulase-positive strains of staphylococci from our patients over the period 1937-1942, and when the first lots of penicillin were received *in vitro* sensitivity studies were carried out with these strains. Every strain proved to be sensitive to the action of the drug.¹⁵

Simultaneously, we found penicillin to be quite effective in the therapy of staphylococcal sepsis.¹⁶ But with the passage of time, we, in common with many other investigators, began to isolate an increasing number of strains of staphylococci that were highly resistant not only to penicillin, but to other commonly used antibiotics.^{17,18}

The problem of antibiotic-resistant staphylococci is primarily one of the large general hospitals, and the essential features of this problem may be summarized as follows: Strains of staphylococci isolated from a hospital population may at first exhibit sensitivity to a given antibiotic, but as that antibiotic is more widely used throughout the hospital, resistant strains of staphylococci make their appearance with increasing frequency. In expressing the degree of resistance, we have stated that a strain is highly resistant when *in vitro* growth of the organisms is not inhibited by fifty units or micrograms of the antibiotic. Under these conditions, at the present time, approximately 70 per cent of the strains being isolated from patients at the Minneapolis General Hospital are resistant to penicillin and to streptomycin; about 50 to 60 per cent are resistant to the tetracycline drugs; and 20 per cent resistant to erythromycin.

The relationship of *in vitro* drug sensitivity to the amount of drug being used generally is beautifully illustrated with chloramphenicol. This drug has had but limited use in our clinics, and as a result only 2 per cent of the strains of staphylococci are resistant.* Other important features of the problem of antibiotic-resistant staphylococci are that resistance is a permanent characteristic of a given strain and its progeny, and resistant strains are just as virulent and invasive as the sensitive

*I am indebted to Miss May Collins for data on these tests.

strains. Finally, the reservoir of these resistant strains is in patients and healthy carriers; the latter including hospital personnel, who harbor the organisms in the nasopharynx, intestinal tract, and on the skin. These carriers, including patients, can readily contaminate the immediate environment, such as blankets, dust, utensils, and instruments. The importance of healthy carriers and patients at the University Hospitals acting as reservoirs of antibiotic-resistant staphylococci was clearly demonstrated by Dr. Robert Wise.¹⁹ He showed that about 30 per cent of the surgical personnel carried coagulase-positive staphylococci in the nasopharynx, and a considerable proportion harbored antibiotic-resistant staphylococci. In contrast, patients coming to the out-patient department, mostly from rural areas, rarely carried resistant staphylococci in the nasopharynx. Since infections caused by antibiotic-resistant staphylococci do constitute a serious problem in the hospitals, particularly on the surgical services, concerted efforts should be made to prevent cross infections, and this can be done as emphasized by Howe.²⁰ In addition, antibiotics like neomycin, bacitracin and vancomycin can be used discriminately in the treatment of severe cases of staphylococcal sepsis due to resistant organisms.

Infections Caused by Gram-negative Enteric Bacteria.—A problem closely related to that of antibiotic-resistant staphylococci involves several species of Gram-negative organisms. Just as staphylococci are found widely distributed, not only in the nasopharynx and on the skin of man, but also in his immediate environment, so this group of bacterial species find their reservoir in the intestinal tract of man and in the surrounding environment. The species of bacteria include *Escherichia coli*, *Aerobacter aerogenes*, *Paracolon bacilli*, *Proteus* species, and *Pseudomonas aeruginosa*. These bacteria are not considered to be very invasive, and may exist without harm in the intestinal tract or on the skin, but localization in the kidneys may produce chronic and debilitating disease, and invasion of the blood stream may result in shock and death. These enteric bacilli continue to cause a number of problems in clinical medicine. Since they parasitize the normal intestinal tract of man, they have been exposed considerably to the various antibiotics, which means that an increasing number of strains exhibit resistance to the

drugs. This development is reflected in the difficulties encountered in the management of chronic infections of the urinary tract, especially pyelonephritis. Bacteremia caused by these enteric organisms is often accompanied by shock, which is caused by a surface bacterial polysaccharide.^{21,22} This shock is reversible if prompt action is taken by administering an appropriate antibiotic, and by using a pressor agent, such as norepinephrine or metaraminol.²³

Since infection with enteric bacilli does constitute such a serious clinical problem, every effort should be made to prevent invasion of the tissues and the blood stream of patients following instrumentation of the urinary tract, elective surgery of the colon, and surgery of the biliary tract.

The Sulfonamides and Antibiotics in Agriculture.—This discussion would not be complete without reference to their use in the control and treatment of infections in animals, poultry and in birds. The antibiotics have been highly successful in the therapy of mastitis in cattle, but less effective for blackleg and anaplasmosis. There is some hope expressed for controlling orinthisis in birds with antibiotics.

Perhaps one of the most spectacular applications of the sulfonamides and antibiotics is their use as food supplements for swine, beef, cattle, sheep and poultry.²⁴ In swine, minute quantities of antibiotics increase the rate of growth 10 to 20 per cent with remarkable savings of expenditures for food. Less definitive results have been reported for cattle and sheep. The antibiotics have a definite growth-promoting effect on chicks. The antibiotics have also been successfully used in poultry and in fish as preservatives. The harmful effects of microbial growth in these foods has been prevented by small concentrations of the drugs. It is doubtful that the present day use of antibiotics in agriculture has any serious harmful effects on public health.

Remaining Problems

Many bacterial infections can now be managed with antibiotics, which in turn has led some scientists to conclude that the sun has set upon the discipline of microbiology, and tempered the enthusiasm for clinical investigations in this field. On the contrary, there still remain many perplexing and fundamental problems to be resolved. Although the advancements in the control and management of

infectious diseases have been remarkable, we still have but very meager information as to why a patient becomes ill, and why a definitive pattern of illness is set up following the invasion of the tissues by microorganisms. Why does the patient parasitized by the influenza virus have a severe headache and pains in his muscles? What is the precise cause of a febrile reaction? Why is the diabetic individual prone to acquire more severe infections than the nondiabetic? What debilitating residuals remain in apparently "normal" people following repeated but unrelated infections? It can be assumed that deranged metabolic functions are the cause of illness, which are set in motion by the interaction of the host and microorganisms. A resolution of these dysfunctions can only be brought about by a study of pathological physiology at the level of the host's cells. This means the utilization of many different basic disciplines, including bacterial physiology, enzymology, chemistry and immunology. For the properly trained individual, microbiology, both basic and clinical, still offers a rewarding field of creative effort.

More specifically, there still remain human infections, such as fungus diseases, that have not yet yielded to effective chemotherapy. The most important of these is histoplasmosis, a disease being seen with increasing frequency. While the majority of cases are mild, and recovery ensues, systemic histoplasmosis, and some instances of pulmonary disease, may be a progressive fatal infection. A more hopeful outlook embraces the therapy of actinomycosis with sulfonamides and penicillin; the treatment of blastomycosis with 2-hydroxy-stilbamidine; and the local application of mycostatin (Nystatin) for oral, vaginal and rectal moniliasis. Preliminary investigations indicate that amphotericin B is effective for cryptococcosis, but therapy is wanting for coccidioidomycosis.

Practically the entire field of virus diseases is open for investigations on chemotherapy. The only infections in this category responding to antibiotic therapy are lymphogranuloma venereum and ornithosis, both diseases being caused by antigenically related large viruses. Trachoma responds to sulfonamide therapy. It is difficult to maintain a very sanguine outlook for chemotherapy in virus infections because the microorganisms are so intimately related to the intracellular metabolism of the host. Therapeutic agents for some of the smaller viruses would have to be exceedingly specific. It is not

unlikely that in the long run immunization procedures will be more effective in controlling diseases due to viruses.

As we take inventory of the vast accomplishments of chemotherapy, the history of medicine has emphasized that no infectious disease was ever treated out of existence. Syphilis and gonorrhea have not been eliminated. Typhoid fever and diphtheria still comprise a serious threat to human health in the most advanced communities. Environmental sanitation and strict public health control of food, water and milk are as essential as ever. One case of smallpox in the City of New York could be the bridge to catastrophe, and the appearance of plague in one of our seaports would justifiably cause alarm. Knowledge of the prevention of disease is every bit as important as its correct management with antibiotics.

Pharmacology of the Tranquilizing Drugs

RAYMOND N. BIETER, M.D., PH.D.
Minneapolis, Minnesota

SINCE the drugs with which we are concerned are best known for their effects on behavior, especially emotional behavior, we might properly begin this discussion with a brief and greatly simplified description of the nervous system structures which are implicated in the control of such behavior.

Cortical Structures

1. Sensory data are projected from the sense organs to highly specific areas in the cortex which must be intact in order to have sensory discriminations. The functions of these sensory projection areas appear to be rather specific. Thus, destruction of the "visual area" in the occipital lobe results in blindness in man, but does not lead to a loss of other sensory processes or motor function, and surprisingly little disturbance with "higher mental processes," unless any of these functions are directly dependent on vision. Included in this part of the cortex are visual, auditory, olfactory, gustatory and tactile senses, and pain.

2. Another large area of the cortex has rather specific functions relating to voluntary motor activity. Lesions in this area may lead to paralysis of specific muscle groups while sensory, and "higher mental processes" are left relatively intact.

3. In the remaining large areas of the cortex there are fewer specific centers to which the other cortical functions are assigned. It is generally assumed that these areas of the cortex function in the control of such complex processes as thought, judgment, learning, remembering, et cetera, but detailed evidence concerning specific function is very limited. There are some indications that judgment may be impaired by lesions in the prefrontal areas, and that parts of the frontal and temporal lobes have important functions in the control of emotional behavior, but no sharp division of func-

tion can be assigned to specific cortical areas on the basis of present evidence.

Subcortical Structures

1. Certain areas, and especially the hypothalamus, are associated with emotional behavior, such as anxiety, fear, anger, worry and the emotional state associated with pleasure. Stimulation of certain areas in the hypothalamus and related diencephalic structures result in behavior similar to that observed under conditions of strong emotion. Conversely, ablation of these same areas may result in extreme placidity and lack of emotional reaction.

2. Closely associated with the above subcortical areas are other regions that appear to exert direct regulatory influences on a wide variety of homeostatic mechanisms. These are the important processes to the organism of circulation, respiration, digestion, etc. These can be maintained in decerebrate animals and appear to be regulated directly by these subcortical neural structures. It should also be noted that this homeostatic regulation depends in large part on the hormonal mechanisms of the endocrine system. The hormone "master" gland, the pituitary, has such a close functional relationship with the hypothalamus that it is impossible to divorce the endocrine aspects of homeostatic regulation, and certain phases of emotional activity, from the action of subcortical neural structures. Stimulation and ablation studies again reveal that these areas are intimately concerned with the homeostatic regulation of many aspects of the internal environment such as blood pressure, pulse rate, blood sugar, and temperature regulation. These changes are mediated primarily through the autonomic nervous system and the endocrine glands. Furthermore, changes in these aspects of the internal environment occur with great regularity, associated with changes in emotional behavior.

3. Subcortical structures are also very much involved in the control of the involuntary muscula-

Dr. Bieter is Professor and Head, Department of Pharmacology, University of Minnesota Medical School, Minneapolis.

Presented at the meeting of the Northern Minnesota Medical Association, Alexandria, September 7, 1956.

ture. This includes both the various smooth muscle structures in the body, and certain striated muscles. Several groups of these striated muscles are those involved in facial expression and posture. The hypothalamus is only one of the structures involved in this function. However, there is good evidence that lesions in this region may interfere with such involuntary muscle control as that involved in emotional facial expression, while voluntary control of these muscles is left intact.

4. One of the other primary functions of this region is simple conduction of impulses over various fiber tracts to and from the cortex, sensory receptors, muscles, and glands. The subcortical areas appear to modify cortical activity and in turn are modified by the cortex. For example, sleep and waking cycles, which are obvious examples of modified cortical activity, appear to be under rather direct control of centers in the hypothalamus. Sleep may be induced or prevented at will by appropriate stimulation, or ablation of these subcortical structures. On the other hand, we have all learned that sleep may be profoundly influenced by such sensory, motor or "psychic" functions, as listening, walking and planning for the future, all of which are presumed to reflect cortical activity. One of the most important aspects of subcortical influences on cortical function involves the so-called "reticular activating system" in the brain stem, midbrain and diencephalon. This system is excited to some extent by any sensory stimulation. It is markedly excited under conditions of emotion. Reticular activity is presumed to increase the general reactivity of the entire cortex. It has been functionally associated with the behavioral phenomena of "alertness," or "readiness to respond."

The assumption is often made that any procedure which affects such "higher mental processes" as decision making must act upon the "higher mental centers" in the cortex. This discussion of the neural mechanisms of behavior is intended to emphasize the complete fallacy of such an assumption. Complex behavior involves the action of sensory receptors, effector organs, and highly complex interactions in the nervous system. Changes in such behavior can be brought about by disturbances anywhere along this chain of functional units.

We now turn to the pharmacology of the most important tranquilizing or ataractic drugs.

Reserpine

This is an alkaloid obtained from the Indian plant, *Rauwolfia serpentina*. The dosage range is from a fraction of a milligram to several milligrams. It can be administered by injection or by mouth. In animals it produces a striking picture of quiet and tranquility. Animals that are frightened or wild become tame and indifferent to danger. The effect of a single moderate dose is produced after a latent period of one or two hours and may last for several days. There occurs no mental confusion, no difficulty of movement and no personality changes. In this respect this drug is strikingly different from the barbitol hypnotics. The electroencephalogram following the administration of this drug shows a relatively normal pattern, whereas barbitol hypnotics show a sleep pattern. Additional effects produced are miosis, an anti-emetic action, hypothermia, increased secretion and motor activity of the gastrointestinal tract, bradycardia and a drop in blood pressure, and abolition of pressor reflexes from the carotid area. Electrical stimulation of the anterior hypothalamic region shows many of these same effects. Therefore, and because reserpine has shown no actions on peripheral structures to account for these actions, the drug is presumed to have its action primarily on subcortical areas such as the hypothalamus. The acute toxicity of the drug in animals is not very great and no chronic toxicity has been observed in animals. The crude plant contains several other alkaloids, some of which are equally active and others not.

Joseph V. Brady,¹ of the Walter Reed Army Institute of Research, has used a behavioral test in rats and monkeys for studying this type of drug. The animals, after being deprived of food and liquid for twenty-four hours, are placed in a container where they learn to press a bar to obtain a small amount of food or a drop of liquid. Soon the technique is changed so that they are awarded with food or drink on an average of only once in sixty seconds. These training periods of several hours are used on a number of days during the week. As a result, the animals can be stabilized on this regime. Then another stimulus is added which consists of a clicking noise lasting three minutes and terminating in an electrical shock administered to the feet of the animal. The animals soon learn to recognize the auditory stimulus terminating in the shock by showing a "fear" or

"anxiety" reaction. This reaction consists of crouching and defecation, and a reduction in bar pressing. This three-minute anxiety-producing stimulus is given at seven-minute intervals. The behavior of the animals during both the three-minute and the seven-minute periods is recorded electrically. The response of the animals can be changed as follows with certain drugs: Amphetamine leads to a 100 per cent increase in bar pressing during the seven-minute, so-called control period, whereas during the three-minute anxiety producing period, the bar pressing is reduced to zero. On the other hand, under the influence of reserpine, bar pressing is reduced 50 per cent during the seven-minute control or anxiety free period, whereas during the three-minute anxiety producing period, inhibition to bar pressing is removed. In other words, the anxiety is not produced or else the animal is made indifferent to the stimulus, and proceeds with its bar pressing at a rate equal to that seen during the original seven-minute so-called control period. Thus it can be said that reserpine tends to block the reactions due to anxiety or fear.

Chlorpromazine

This is a synthetic drug introduced in France in 1953.² It is related chemically to certain antihistaminic drugs but of itself does not have this action. The dosage range, generally given by mouth, varies from 50 to 100 mg. repeated several times in twenty-four hours. Like reserpine, this drug also produces quiet and tranquility in animals. The action comes on more rapidly and is of shorter duration than that produced by reserpine. Again, anxiety and fear in animals tends to be changed to indifference. Neither drug will produce full hypnosis or general anesthesia. This drug, in the experimental animal potentiates various barbitol hypnotics, ether and alcohol. For the latter drug it also suppresses psychomotor excitement and increases toxicity. It does not potentiate analgesics. It potentiates the action of certain synthetic curare-like drugs but does not reduce toxicity. It is not anticonvulsant. In addition, in experimental animals, the drug also is anti-emetic, produces hypothermia and depresses thermoregulation, reduces gastric secretion, blocks pressor reflexes arising in the carotid area, may produce a slight fall in blood pressure, shows a strong

blocking action against epinephrine and will prevent death in an animal from up to six lethal doses of epinephrine, blocks norepinephrine or levarterenol slightly, blocks edema and capillary injury produced by certain drugs by an action not associated with histamine block and has a weak analeptic action against the laboratory anesthetic, urethane. Again it appears that this drug, like reserpine, acts on subcortical areas, perhaps chiefly the hypothalamus. The mechanism of action of these two drugs has been extensively studied. In the present state of our knowledge these mechanisms appear to be quite unlike.

Preston³ has submitted a possible mechanism of action for chlorpromazine from studies on the central nervous system in the cat. He used a dose (10 mg. per kg. body weight) within the human clinical dose range which also produced a tranquilizing action in the cat. He found that the drug increased nervous discharges from the amygdala to the hypothalamus and that this increased discharge into the hypothalamus depressed or arrested the activity of this region. Depression of the hypothalamus, as far as can be determined, could account for the typical tranquilizing action of this drug. Stimulation and ablation studies in this region support this mechanism of action. As the dose of chlorpromazine is increased, this increased discharge rate of nervous impulses spreads to other areas leading ultimately to generalized convulsions. This effect appears to be similar to the action of this drug in man, where a Parkinsonian type of convulsion has been reported. Preston, and other workers also, have found that the depression of the reticular activating system produced by chlorpromazine is slight. Therefore, the above described actions take on mere significance.

Heistad,⁴ at Minnesota, has studied the action of chlorpromazine on a conditioned emotional response in rats using a technique similar to that used by Brady in his study of reserpine. The results obtained were similar, although at a dose of 2.5 mg. per kg. of body weight given in intraperitoneal injection, the ability of chlorpromazine to block the reactions due to anxiety or fear was not as great as Brady reported with reserpine.

There are several other members of the group of tranquilizing drugs. These drugs for which we have even less pharmacologic knowledge are the following:

Meproamate, Miltown, Equanil.—This drug also appears to have an action chiefly on subcortical regions of the brain.⁵ It produces the same quieting effect with indifference to fear characteristic of the other drugs under consideration. It also inhibits the righting reflex and in large doses produces a reversible flaccid paralysis of skeletal muscle. Further actions include its ability to produce a slight drop in blood pressure and pulse rate, an ability to potentiate barbitol hypnotics, a protective action against strychnine convulsions and a protective action against the extensor phase of electroshock seizures. Hendley and his associates⁶ found that Miltown caused a marked synchronization with moderate slowing of the frequency of brain waves in the experimental animal. This might suggest a mechanism of tranquilizing action for this drug, because the reverse type of brain waves, namely asynchronous activity, is responsible for a normal waking record.

In man, the dose of this drug begins at 100 to 200 mg. given several times a day. Dickel and his associates⁷ have studied the action of this drug in patients with neuromuscular tension and anxiety. In addition to relieving the anxiety, the drug was found to have another action: using the electromyograph they found better relaxation of muscles on the one hand and improved co-ordination of muscles on the other. If this effect is confirmed, it would indicate that the muscle relaxing action of the drug is of some value.

Azacyclonol HCl, Frenquel.—This drug is antagonistic to cerebral stimulants in mice and rats, and to the CNS stimulation produced by morphine in cats.⁸ It also potentiates the action of barbitol hypnotics. It has one other interesting known action. The chemical lysergic acid diethylamide produces schizoid changes (hallucinations) in man when given in minute doses. This disturbance can be rapidly terminated with Frenquel. The dose of this drug begins at 15 mg. repeated several times a day.

Promazine, Sparine.—Chemically this drug is chlorpromazine minus a chlorine atom. With this close chemical relationship it is not surprising that its action is very like that of chlorpromazine. In studies reported to date it appears to produce almost identical pharmacologic effects. The dosage of promazine is the same as chlorpromazine.

Indications for the Use of these Drugs

These drugs are indicated chiefly in psychiatric disorders characterized by the symptoms of excitement, delirium, tension, agitation, anxiety, worry, fear and depression. These symptoms of themselves are not of extreme importance, for every normal individual at times experiences one or more of them. Most normal individuals learn in the process of growing up how to use these emotions for improving their education, or living, or working surroundings or associations with other individuals. It can be said then, that these emotions can and do serve a useful purpose. At times, however, the stimulus leading to one or more of these emotions may be extremely intense and prolonged, as for example during a catastrophe, or during a self-limited illness, such as delirium tremens. In certain of these instances a physician is justified in considering a limited use of one of these drugs. On the other hand, in certain clinical disease entities, such as schizophrenia, these symptoms may become so powerful that they lead to a marked and prolonged alteration in behavior relating to the patients surroundings of physical objects, and other individuals. Various forms of therapy are in use, and a certain measure of success is attainable with each, but no therapy is known to date that is successful in every patient. Only one other drug therapy will be mentioned. The above types of emotions in both normal individuals and in psychiatric patients can be fairly well controlled with barbitol hypnotics. These drugs have an over-all and marked depressant action on the entire central nervous system. As a result, in order to obtain emotional control, the barbitals will produce additional actions such as sleepiness, hypnosis, disturbed and dulled mentation, and various degrees of motor incoordination. In this condition, patients obviously cannot take care of themselves.

The ataractic drugs, on the other hand, appear to act by producing a block or inhibition at one or a few relay centers in the neural pathways associated with the abnormal behavior produced by emotional overactivity. This action appears to be on the subcortical areas, thus leaving the cerebral areas, necessary for our highest mental processes, in a relatively normal condition. As a result, when the stimuli to abnormal behavior are removed or the patient becomes indifferent to these emotions,

he or she can carry on a much more normal day-to-day life.

It should be emphasized that these drugs produce only symptomatic relief. No evidence is available that they are curative. Whether long-time use of one of these drugs by blocking abnormal behavior can lead slowly to the initiation of nervous impulses elsewhere, perhaps in the cerebrum, to depress or inhibit the origin of these persistent and therefore troublesome emotions, remains to be proven. Thought processes may be abnormal or pathologic in disease entities. There is no evidence that the ataractic drugs can change these abnormalities in a normal direction.

Unfortunately, too, the use of these drugs has brought with it a number of side effects. Chlorpromazine and reserpine may cause extra pyramidal disturbances like Parkinsonism. Sometimes only after a disturbance of this type does the drug show any benefit. This disturbance suggests a facilitation of motor nervous impulse conduction. It can be controlled with a drug like tri-hexphenidyl HCl (Artane HCl) given concurrently. If control is obtained, the ataractic drugs need not be discontinued. Chlorpromazine may produce convulsions or agranulocytosis. It would appear that in these instances the drug should be discontinued. Chlorpromazine may produce jaundice. One school of thought, believing this due to an obstruction in the biliary passages which is self limited, suggested that the administration of the drug may be continued. Another school of thought believes this to be an allergic manifestation and that the drug should be discontinued.⁹ Both reserpine and chlorpromazine have been known to produce depressive psychotic reactions (over 200 have been reported with reserpine as of June, 1956). This suggests that the drugs change the emotional status with resulting behavioral effects but not necessarily in the direction of normal. Reserpine, being the chief offender, should not be used in depressive states. Because reserpine increases gastric secretion it should not be used in gastric disturbances. Whether the newer drugs in this series are less prone to produce side effects or not remains for the future to prove. Drowsiness and allergic reactions are a possible side effect with any of these drugs. DeFeo and Reynolds¹⁰ have reported that reserpine can disturb the menstrual cycle in the Rhesus monkey.

This effect therefore is a possible side effect in human patients.

A caution concerning the use of reserpine has recently been made available by Dr. Ralph G. Smith¹¹ of the Food and Drug Administration, Washington, D. C. He has collected data on the clinical use of this drug from which the following conclusions have been drawn: (1) A dose of 0.32 mg. of reserpine per day raises the gastric secretion and gastric acidity in a significant number of cases; (2) a dose of 0.5 mg. of reserpine per day for a period of two weeks produces the same change in acid secretion in most patients and this has resulted in massive gastrointestinal hemorrhage and ulcer perforation; (3) a dose of from 0.5 to 1. mg. per day has produced severe depression in a significant number of patients and has precipitated a number of suicidal attempts; (4) a dose of 0.75 mg. per day and up should be given to patients only in a hospital and under careful supervision; and (5) a dose of 0.25 mg. of reserpine per day has shown none of the above untoward effects.

Summary

A group of drugs with pharmacologic actions quite different from that of any other group of drugs has been introduced into medicine. This group, the ataractic drugs, appears to effect chiefly emotions and thereby emotional behavior. However, serious side effects and the danger of overuse and abuse are important reasons why physicians should use them judiciously. It is possible that overuse, which may be a distinct abuse in many patients, may do more harm than good in our civilization.

Treatment of Communicating Hydrocephalus by Spinal Subarachnoid-Omental Bursa Shunt

Preliminary Report

HENRY W. DODGE, JR., M.D.
WILLIAM H. ReMINE, M.D.
MILAM E. LEAVENS, M.D.
Rochester, Minnesota

THE lack of a consistently satisfactory surgical treatment for communicating hydrocephalus, whether congenital or acquired, has remained a frustrating obstacle despite the best combined efforts of physicians and surgeons concerned with patients so afflicted.

That no one procedure for the control of this condition has proved completely adequate in the past is well attested to by the large number of operations devised to divert the cerebrospinal fluid to various extranevous depots, potential or real. To list the types and forms of surgical material employed in accomplishing such diversion of the cerebrospinal fluid is to give testimony to the ingenuity of physicians, past and present, and to the astounding tolerance of the human organism for foreign bodies.

When the ventricles of the brain communicate freely with the spinal subarachnoid spaces, and the basic difficulty resulting in progressive internal hydrocephalus is the apparent inability of the cerebrospinal fluid to gain egress (to be adequately absorbed) from the central nervous system, the resulting condition has been termed "communicating hydrocephalus." It may be congenital or acquired following inflammatory changes in the brain and spinal cord.

Some few persons maintain, in contradistinction to this explanation, that the basic defect is one of overproduction of cerebrospinal fluid rather than faulty absorption. However, whatever the underlying mechanism, the commonest surgical procedures devised have been those by which an attempt has been made to deposit the excess of cerebrospinal fluid in an extranevous depot.

Dr. Dodge is in the Section of Neurologic Surgery, Mayo Clinic; Dr. ReMine is in the Section of Surgery, Mayo Clinic and Mayo Foundation; and Dr. Leavens is a Fellow in Neurosurgery, Mayo Foundation.

The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

The pertinent literature is exceedingly large and many operations have been described. In the main those operations designed to lead the cerebrospinal fluid from the spinal lumbar sac to the subcutaneous tissues of the back (seton procedure), to the interstices of the vertebral bodies, or through the vertebrae to the retroperitoneal space, to the ureters, to the abdominal cavity either intraperitoneally or retroperitoneally, to the Fallopian tubes, or to the urinary bladder have been used most frequently.

After a review of our own results with various types of shunting procedures designed to relieve communicating hydrocephalus and talking with Dr. Jorge Picaza¹ of Havana, Cuba, it was decided to shunt the cerebrospinal fluid from the spinal subarachnoid space to the lesser omental bursa. The operation is relatively simple and can be done by the neurosurgeon, or jointly by a neurosurgeon and an abdominal surgeon.

The patient, after suitable premedication, is anesthetized with sodium pentothal, curare and nitrous oxide, and oxygen is administered in liberal amounts. An endotracheal airway is always employed. In infants and small children, ether with an endotracheal airway is used. A plastic intravenous cannula or needle of large caliber is always inserted prior to the positioning of the patient on the operating table. The indifferent electrode for the electrosurgical unit is placed routinely on the right thigh (the up side) to avoid undue pressure or venous stasis.

With the patient placed in the lateral decubitus position with the right side up, the skin is prepared over the entire operative field, abdomen and spinal column. The patient is then draped so that the fields of the two incisions are included. Thereafter, the abdominal site is draped out of the field until after the operation on the spinal column. An operating table adaptable to lateral

tilting is used and the patient is tilted, with his head lower than his feet, into a position that makes the spinal column more accessible than

Fig. 1. Diagram showing anatomic structures and placement of the polyethylene tube connecting the spinal subarachnoid pathways with the lesser omental bursa.

it is with the patient in the direct lateral decubitus position.

A midline incision is made over the upper lumbar vertebrae and laminectomy is performed at the level of the first lumbar vertebra on one or both sides depending on the age and size of the patient. The spinal dura is opened, a polyethylene tube of appropriate size for the patient is threaded down into the spinal cul-de-sac after three or four lateral perforations are made in the tubing, and the dura is resutured. The polyethylene tube is then ready for introduction through the paravertebral muscles into the peritoneal cavity. It is anchored by silk sutures. The curve of the tubing is usually very gentle.

After the polyethylene tube has been put in place in the spinal subarachnoid space, a transverse incision is made in the right upper abdominal region. The incision extends from just beneath the thoracic cage to a point approximately 1.5 inches above the umbilicus. The right rectus muscle is then retracted medially and the peritoneum is opened. The stomach and colon are delivered from the abdomen, an opening is

made through the gastrocolic omentum, and a long curved forceps is passed through the lesser omental space and out the foramen of Winslow. The polyethylene tube is passed through the paravertebral muscles, grasped by the curved forceps previously placed and pulled into position in the lesser omental space. Four to six small holes are made at 1-inch intervals in the side of the tube and the tube is irrigated with a saline solution containing six units of heparin per cubic centimeter. The tube is then coiled loosely and placed within the lesser omental space so that it lies flat behind the stomach. Placement of the tube in this position prevents omentum and intestines from becoming adherent around the openings in the tube and thereby helps to avoid obstruction (Fig. 1). The opening in the gastrocolic omentum is closed with a continuous suture and the operation is completed.

The postoperative course is usually uneventful. For the first two to three days the foot of the patient's bed is elevated to prevent too marked emptying of the ventricles. The foot of the bed is gradually lowered over the ensuing few days. Abdominal sutures are removed on the seventh day after operation, or the wound may be closed with a subcuticular stitch. The skin sutures in the spinal incision are removed on the seventh to eighth day after surgery.

Except for infants, the patients are permitted to walk on the third or fourth day after the operation; they are often ready to leave the hospital by the tenth day.

The report following is an example of a rather typical case in which this procedure has been employed.

Report of a Case

Case 1.—A baby girl, whose birth via breech delivery had been without difficulty, was jaundiced, listless and did not feed well on the morning of her fourth day. Examination at the Mayo Clinic revealed a four-day-old, jaundiced, listless girl whose temperature was 98° F. The pulse rate was ninety-six beats per minute and respirations were recorded at eighteen per minute. Circumference of the baby's head was 37 cm. The anterior fontanelle was noted to be full and tense. Stimulation caused the child to give a weak cry but she moved all her extremities well. Her deep tendon reflexes were hypoactive. On examination, the eye grounds appeared normal; clinical examination of her heart, lungs and abdomen did not reveal any abnormality. Roentgenograms of the head and thorax were reported as within normal limits. The concentration of hemoglobin was 13.1 gm. per 100 cc. of blood. The

erythrocytes numbered 3,070,000 and the leukocytes, 3,100 per cubic millimeter of blood. Routine analysis of the urine gave normal results, and cultures of venous blood did not show growth of organisms.

Subdural taps were carried out because of the possi-

On March 12, 1954, ventriculography, dye studies and insertion of a silk seton² were carried out. The ventricles were tapped through the anterior fontanelle and a clear colorless fluid was obtained under pressure. The ventricular fluid was analyzed and found to contain

Fig. 2. (a) and (b). Appearance of the child in the case reported herein, one year after the shunt (April, 1955). (c). The same child's appearance two years and three months after subarachnoid omental-bursa shunt (July, 1956). Note that from the appearance of shoulders and arms the child's body is beginning more nearly normally to approximate the proportions of the enlarged head.

bility of the existence of a subdural hygroma or hematoma but the results were negative. Lumbar punctures were carried out, the first of which revealed bloody cerebrospinal fluid containing 240,533 erythrocytes and 1,800 leukocytes per cubic millimeter. The child's condition improved during her hospital stay of fourteen days. At the time of her dismissal she was feeding better, her jaundice had disappeared, the anterior fontanelle was soft and flat and the circumference of her head was 38 cm. It was felt that she had suffered an intracranial hemorrhage during or subsequent to labor, and the prognosis for normal mental development was considered guarded.

When the child was four months of age, her family physician referred her back to the clinic because her head was increasing in size faster than it should. The only unusual thing noticed by her parents in her otherwise normal development was that the child seemed unable to keep her eyes fully open.

Examination at this time revealed that the child was hydrocephalic with a large head and "setting sun" characteristic eyes. The anterior and posterior fontanelles were bulging and tense and the sagittal suture was separated. A cracked-pot sound was noted on percussion of the head. In the occipital region a hemangioma of the scalp was present. The circumference of the head was 46.5 cm., an increase of 8.5 cm. since the baby's first admission four months previously. Vision and hearing seemed intact. The child was alert, moved her extremities well, but had some difficulty lifting her head. Nystagmus was noted on lateral and attempted upward gaze. There appeared to be a paralysis of upward gaze and retraction of the upper lids. Results of the general examination and the examination of the eye grounds were within normal limits. Roentgenograms of the skull now showed a large, thin calvarium with bulging of the anterior fontanelle.

a total protein of 10 mg. per 100 cc. and a cell count of one lymphocyte. Roentgenograms made after 2.5 cc. of indigo carmine was placed in the lateral ventricles showed marked dilatation of the lateral ventricles without shift and without filling of the third and fourth ventricles. Half an hour after the dye had been introduced, a lumbar puncture was done; it showed dye in good concentration. The results of these tests suggested the presence of a communicating hydrocephalus. A silk seton was placed in the lumbar region³ to connect the lumbar subarachnoid space and the lumbar subcutaneous tissue and allow drainage of cerebrospinal fluid. At the time of the child's dismissal the circumference of her head was 48 cm. The family physician and her parents were instructed to measure the circumference of her head at frequent intervals and record it.

During a three-week period the circumference of the child's head increased 1.5 cm., and it was believed that the seton was not relieving the intracranial pressure adequately. Consequently, on April 5, 1954, an encephalogram was made to establish the patency of the cerebral aqueduct. It was found to be patent.

On April 7, 1954, a procedure was carried out whereby the cerebrospinal fluid was shunted from the lumbar subarachnoid space to the lesser omental bursa. The procedure was tolerated well by the child and her convalescence in the hospital was uneventful. She was dismissed to go home on the tenth day after operation, with her wounds healed and the sutures removed.

The child was re-examined in July, 1956, at the age of two and one-half years, and two years and three months after the operation. Her development, both physical and mental, has been most satisfactory, and she is considered normal by her parents. Her head is still large, however, in proportion to her body, but she has lost most of her hydrocephalic features, such as the "setting sun" eyes Fig. 2(a), (b) and (c).

At this time (July, 1956) our experience with the shunting of cerebrospinal fluid from the subarachnoid space to the lesser omental bursa has been limited to twenty-six patients, of whom twenty-three were infants and three adults. This paper is a preliminary report of our use of the procedure. The need of further time and more experience is well recognized as absolutely essential before any valid conclusions can be drawn as to the real efficacy of such a shunt in cases of communicating hydrocephalus to allow for adequate cerebral compensation.

However, our very limited experience to date suggests that such an operation may offer certain advantages to the patient until the time when medical science has developed enough to allow a more definitive attack on the basic underlying cause of the pathologic entity.

Spinal subarachnoid-omental bursa shunt can be employed with equal ease in tiny infants and adults of either sex. The loss of blood incidental to the operation is minimal, shock is negligible and convalescence is usually uneventful. Since the cerebrospinal fluid is reabsorbed by the body, electrolyte deficiencies are not encountered as with other procedures.

No organ is sacrificed and there is no need for preliminary intravenous pyelography, tests for renal function and so forth or for such things as mechanical valves, end buttons, connectors, or

joints. Such theoretical possibilities as plugging of the shunt by omentum are avoided. Extra lengths of tubing can be left in place to allow for growth if the patient is an infant. The caliber of the tubing can be practically unlimited except for the tiniest of infants. Patency of the tube can be checked subsequently by making roentgenograms after radiopaque substances are placed in the spinal subarachnoid space. Early ambulation can be practiced without fear of dislodging the tube; should ultimate failure of the shunt occur, other avenues of surgical treatment are still open.

Our experience to date with spinal subarachnoid-omental bursa shunt suggests that this procedure may have some merit and that it is worthy of trial and observation in the attempt to alleviate the ravages on the central nervous system of progressive communicating hydrocephalus, whether it be of congenital or inflammatory origin.

Staphylococcus Infection in a Nursery for Newborn Infants

JOAN WILLIAMS, R.N., B.S.,
PETER ODENBRETT, B.S.,
ARNOLD S. ANDERSON, M.D.
Minneapolis, Minnesota

ON September 10, 11 and 14, 1955, cultures of inflamed umbilical areas of three newborn infants revealed coagulase positive staphylococci with identical antibiotic sensitivity patterns. It was believed this was sufficient evidence to suspect an epidemic in the newborn nursery. On September 15, definite steps were taken to locate the source of these infections.

The following plan was followed:

1. Inspection and routine nose and throat cultures of personnel of the delivery room, obstetric floor and newborn nursery were done within twenty-four hours.
 2. The personnel in the delivery room, on the obstetric floor, and in the newborn nursery were reinstructed regarding the importance of reporting anything other than normal symptoms concerning their own persons.
 3. Personnel were thoroughly reoriented to the principles of individual technique to be used in the nursery.
 4. The autoclaves were checked.
 5. Cultures were taken from delivery room packs, transfer forceps, nursery table equipment and solutions.
 6. The situation was reported to the State Board of Health.
 7. An inspection was made by the State Board of Health Pediatric Consultant, and his suggestions for changes were carried out.
- The hospital director of nurses assumed the administrative responsibility for the investigation. The hospital bacteriologist did the laboratory studies, and an intern made the inspection of personnel; he also secured routine nose and throat and other indicated cultures.
- The physical inspections and cultures were done on twenty-six people. All the cultures were collected on sterile cotton tipped applicators and

inoculated immediately on blood agar plates; and incubated at 37 degrees centigrade. These cultures were examined at twenty-four and forty-eight hours for the presence or absence of coagulase positive strains of staphylococci. Simple disc antibiotic sensitivity tests were done, and the cultures were sent to the University of Ohio Bacteriology Department for phage typing. On September 16, the day following the investigation, two additional cases of omphalitis occurred in the nursery.

TABLE I. ANTIBIOTIC SENSITIVITY TESTS ON STAPHYLOCOCCI FROM NEWBORNS 1955

Baby	Birth	Onset	Antibiotic Discs							
			P	E	F	T	C	S	B	G
1	9/ 6	9/10	+	+	+	+	+	+	+	±
2	9/ 7	9/11	+	+	+	+	+	+	+	±
3	9/ 8	9/14	+	+	+	+	+	+	+	±
4	9/12	9/16	+	+	+	+	+	+	+	±
5	9/13	9/16	-	+	+	-	+	-	+	±

P—penicillin
T—tetracycline
B—bacitracin
F—nitrofurazone

E—erythromycin
C—chloramphenicol
G—Gantrisin®
S—streptomycin

Our physical inspection revealed that one of the personnel, a nurse's aid who worked the night shift in the nursery, had a respiratory infection manifested by a mucopurulent exudate in her posterior pharynx. Seven of the twenty-six nose and throat cultures, including one from the aforementioned nursery aid, were positive for coagulase-positive staphylococci. The cultures taken from the equipment and solutions in the delivery room and nursery were sterile.

The strain with which we were dealing did not react to any of the specific phage types available, but these slides demonstrate the results of the disc antibiotic sensitivity tests upon the coagulase positive staphylococci taken from the umbilical area of the babies and the noses and throats of the hospital personnel.

It will be noted that the antibiotic sensitivity pattern of the staphylococci from Baby 5 is dif-

Miss Williams is Associate Director of Nurses and Mr. Odenbrett is Bacteriologist at Mt. Sinai Hospital, Minneapolis. Dr. Anderson is a staff member in the Department of Pediatrics, St. Louis Park Medical Center.

ferent from that of the other four, though clinically the infection was identical to and occurred at the same time as the other four. This can be explained by the fact that the umbilical area of Baby 5 was treated topically with Neomycin for a day prior to securing the umbilical culture.

TABLE II. ANTIBIOTIC SENSITIVITY TESTS ON STAPHYLOCOCCI FROM PERSONNEL

Personnel	Antibiotic Discs

Though seven persons of the hospital personnel who contacted these babies were carrying coagulase-positive staphylococci in their throats at the time of examination, only one of them (namely, the nursery aid) was carrying an organism whose antibiotic sensitivity pattern matched those of the babies involved in the epidemic. She was also the one person who manifested respiratory disease on the physical inspection.

When this nurse's aid was relieved of her nursery responsibilities, the staphylococcal infection amongst the newborns ceased to occur.

As is often the case, the violation of well-established practices of preventive pediatrics resulted in the unnecessary exposure of the newborns to a potentially serious illness. The nurse's aid who was the carrier had been away from work ill the day preceding recognition of the first case of omphalitis. When she returned to work at midnight, it was decided it would not be necessary to awaken the house officer for the purpose of filling out the routine back-to-work form. The nurse's aid also had a sore throat for several days following her return to work, but apparently did not realize that a "sore throat" was classified as a "self-reportable illness."

All of these cases of omphalitis were minimal in extent. Four were manifested by slight peri-umbilical erythema and one had streaks extending up the abdominal wall in addition to peri-umbilical erythema. None of the infants manifested any symptoms of sepsis. The infants were isolated and their infections responded quickly to

treatment; there have been no complications subsequently observed.

Since this experience, we have been watching for further outbreaks of staphylococcal infections occurring in the infants in the nursery or becoming manifest after they leave the nursery. Many cultures have been taken on suspicious skin and eye lesions, but not until almost a year later was another staphylococcal infection diagnosed. On September 7, 1956, the nurses discovered on a routine admission an impetiginous bleb on an infant boy. The infant was isolated, and the lesion was cultured and treated. Two days later a second infant in the nursery was noted to have an infection in the right eye and an infected area in the left groin. This infant was isolated, her lesions were cultured, and local treatment commenced, but the following day she had several moderate sized blebs in the vulvar area and purulent vulvulitis. Systemic treatment was started, and the lesions promptly regressed and she recovered. The cultures from the lesions of both these infants grew out coagulase positive staphylococci whose antibiotic sensitivity patterns were identical. The mother of the infant boy who was born with a staphylococcal impetiginous lesion manifested no signs of infection during her prenatal, paranatal or postnatal course, although a routine blood count taken from her the day following delivery revealed a WBC of 15,200 with a differential count of 88 per cent polymorphs, 10 per cent lymphocytes and 2 per cent monocytes.

No additional staphylococcal infections have been noted in the nursery since the time of this last outbreak. Moreover, we are aware of none that could have originated in the nursery and become manifest after discharge.

The potential seriousness of staphylococcal disease in the newborn age group requires no emphasis to this group here tonight. We have all had the difficult privilege of caring for a tiny infant with staphylococcal sepsis or its complications. At the fall meeting of this Society in 1955, Dr. Richard Smith reported a staphylococcal epidemic in the newborns at the University of Minnesota Hospitals. His report indicated that, although an epidemic might first manifest itself in minimal skin lesions, it could crescendo into serious and possibly fatal complications.

These experiences tend to confirm our opinion

The Diabetic Foot

B. F. FULLER, M.D.
Saint Paul, Minnesota

ONE OF the greatest challenges to the practicing physician is presented by those patients who have diseases for which there is no real cure and whose treatment consists of an attempt to prolong useful function for as long a period of time as is possible. One such peripheral vascular disease which is frequently seen is the "diabetic foot." This may first be seen in an advanced and serious form or it may have signs and symptoms which are of minimal significance. Either way, it poses a difficult therapeutic problem.

For purposes of our discussion it is necessary to distinguish the "diabetic foot" from simple arteriosclerosis obliterans. Although simple arteriosclerosis obliterans may occur in the diabetic as well as in the nondiabetic patient, it differs from the "diabetic foot" problem mainly in that it is a much more discrete entity clinically. For example, the sequellae to simple arteriosclerosis obliterans (ulceration, gangrene, et cetera) may be related to various etiologic agents, but the primary difficulty is clearly ischemia. By comparison, in the form of arteriosclerosis obliterans which we designate as the "diabetic foot," the same sequellae may occur but other factors than ischemia are often of prime importance. The treatment and prognosis of this form of arteriosclerosis obliterans in the person with diabetes may also be quite different from that of uncomplicated arteriosclerosis obliterans.

Ischemia is always an important factor in the development of this lesion. However, even here it differs from simple arteriosclerosis obliterans. Frequently, one sees extensive ulceration and gangrene of the distal end of the foot with palpable dorsalis pedis or posterior tibial pulses or both present. At an earlier stage of its development one may demonstrate marked pallor of elevation of a toe with absence of pallor of the remainder of the foot and with normal arterial pulsations present. In other words, the arterial insufficiency is usually in the small vessels and frequently is distal to the palpable pulses.

Infection is another important etiologic agent in the development of the diabetic foot. This

usually starts as trichophytosis with the development of maceration and fissures between the toes. This may become secondarily infected with bacteria and extend into the foot. Careful examination is necessary to determine the extent of the infection. Frequently an abscess is present within the foot. Osteomyelitis may be present.

Perhaps the most often overlooked abnormality, and an exceedingly important one, is the presence of anesthesia or hypesthesia of the distal portion of the extremity due to diabetic neuropathy. The adverse effect of trauma on ischemic tissue is obvious. Less obvious is the increased amount of trauma sustained by an anesthetic foot.

The importance of each of the above factors has to be considered separately in the genesis of the lesion in every patient. This is done by means of a careful history, physical examination, and neurologic examination. It must be done before any treatment can be considered. If treatment is to be successful, it must be directed toward the most important etiologic factors and not necessarily toward the ischemia alone.

The initial treatment of the diabetic foot is almost always very conservative. The only exception to this is the presence of an acute, fulminating infection which represents an emergency. This is rarely encountered since the antibiotics have come into general use. The following factors are of importance in therapy:

1. Infection is almost always present to a variable degree. Antibiotics are usually indicated (this is in contrast to the therapy of simple ischemic ulcers where antibiotics are necessary only infrequently.) Infection of the superficial tissues is also treated initially with continuous wet packs (usually of a saturated solution of boric acid).

2. It must be remembered that the ischemic tissues are very friable. Excessive heat and excessive cold must be avoided. The optimal temperature is 85 to 95 degrees. Another common error in treatment is to elevate the foot if it is swollen. This further intensifies the ischemia and should be avoided. The leg should be kept level.

3. If there is any evidence of an abscess it should be drained.

4. A roentgenogram of the foot should always be taken to determine the presence or absence of osteomyelitis.

Very often the ulcerated lesion will heal with conservative management alone. The patient must then be carefully instructed in regard to the subsequent care of his foot to prevent a recurrence. This instruction must include specific advice in regard to foot hygiene (including fungus control). The patient must also avoid trauma from walking barefoot or wearing ill fitting shoes. The extremity must not be exposed to excessive heat or cold, and self medication of minor abrasions and fissures must always be avoided.

If it becomes apparent during treatment that the lesion will not heal, and that a useful extremity cannot be saved, one must then consider the various surgical procedures that may be used:

1. Amputation of several or all of the toes. This has its greatest value in those patients whose problem is recurrent infection and subsequent ulceration in the spaces between the toes. The procedure is helpful in that it enables the patient to maintain better control over fungus infections. It obviously must be done only in very carefully selected patients where the degree of ischemia is minimal. However, in carefully selected patients the wound will heal, and the useful life of the extremity will be considerably prolonged.

2. Transmetatarsal amputation. The indications for this are essentially the same as for amputation of a toe. It is done when the amount of tissue loss or the degree of ischemia are considered too great to permit healing of a lower amputation. It must be emphasized again that these patients must be selected with extreme care as low amputations rarely heal if the extremity is grossly ischemic. In general, it should be said that

at least one of the pedal pulses should be present, that there should be no gross evidence of ischemia of the proximal portion of the foot, and that there should be no evidence of diabetic neuropathy or of osteomyelitis present before one considers doing a transmetatarsal amputation.

3. Higher amputations. Below knee and above knee amputations are done primarily if the degree of ischemia present is enough that a lower amputation will not heal. There is no disagreement on this point. In the diabetic foot there may be another reason for doing a higher amputation. If a significant sensory impairment is present at the amputation site, the wound will probably soon break down even if an adequate enough blood supply is present to enable it to heal. This is a very important consideration. We feel that when amputation is indicated in the diabetic patient it should never be done below the level of sensory impairment.

4. Lumbar sympathectomy. Although we have liberalized our criteria for selection of patients with occlusive arterial disease for sympathectomy very considerably in recent years, and although we feel that it is a very valuable procedure in well-selected patients, we feel that it is rarely, if ever, indicated in patients with a diabetic foot.

The purpose of this discussion has been to re-emphasize and to present in an orderly manner some of the problems encountered in the diagnosis and treatment of one of the peripheral vascular diseases. It is an accepted fact that effectiveness of therapy is directly proportional to its specificity. If we study our patients carefully and attempt to assess correctly the relative importance of the various etiologic factors in the genesis of their lesion, we will be in better position to treat as specifically as possible. The net result will be that many more extremities will be salvaged.

755 Lowry Medical Arts Bldg.
St. Paul 2, Minnesota

FILM ON URINE SUGAR ANALYSIS AVAILABLE

The film, "Urine Sugar Analysis for Diabetics," developed in co-operation with the medical profession, is available at no charge to the medical and allied professions through Ames Company, Inc.

The film was made as a visual aid to be used in the education of diabetic patients and shows the relationship between carbohydrates and insulin. It also explains in lay language the meaning of various diabetic

conditions. It has been produced on 16 mm. film in color and sound track with a running time of approximately 10 minutes. Appropriate "hand-out" literature accompanies the film.

Showings at diabetic clinics, diabetic lay societies and other diabetic groups must be requested by the medical or allied professions to Ames Company, Inc., Elkhart, Indiana, or an Ames representative.

Hypnosis in Obstetrics

WALTER BAER, M.D.
Saint Paul, Minnesota

HYPNOSIS is still a controversial subject. The purpose of this presentation is to evaluate and discuss the use, the disadvantages and advantages of hypnosis in obstetrics.

Hypnosis, at the present time, is still meeting with some resistance by the medical profession, although there is greater acceptance in Great Britain. The British Medical Association has officially recognized hypnosis as a useful adjunct in medical practice. Patients who have experienced hypnotic anesthesia for childbirth are unanimous in their approval.

Although hypnosis is a young science, it is rapidly assuming the dignified position it deserves in obstetrical anesthesia. Some universities, such as University College of Los Angeles, Marquette, Texas, and Yale, have teaching classes in hypnosis.

The Use of Hypnosis

Many doctors use hypnosis when they practice Dr. Read's natural childbirth. His relaxation exercises are merely modifications of hypnotic techniques. With this method about twenty-five per cent of patients could be carried through the early stages of delivery without the use of sedation or anesthesia; however, this kind of hypnosis is not effective in the second stage and cannot be used to perform episiotomy or repair without some degree of medical analgesia or anesthesia.

We are indebted to Dr. Read's epochal work however, for having made women cognizant of methods for pain relief other than noxious drugs and anesthetic agents.

I do not wish to imply that hypnosis will ever supplant anesthesia; however, when the use of hypnosis in childbirth is better understood more patients will be receptive to its use and physicians, in turn, will be less resistant to the concept and technique.

Hypnosis is a serious and useful science that should be left in the hands of experts who understand its usefulness as well as its limitations.

Presented at the meeting of the Minnesota Obstetrical and Gynecological Society, Rochester, Minnesota, September 22, 1956.

Disadvantages

Harm would result from the hypnotist's failing to remove a post-hypnotic suggestion completely, thus possibly causing the subject to react with a stiff leg or arm for some days, weeks, or months after he had been hypnotized.

Hypnosis has its limitations in that not all expectant mothers are satisfactory subjects for the induction of complete anesthesia. The number, about three out of five, with whom it would be effective could be greatly increased if time were taken to teach them to become good subjects.

The time required to produce hypnotic anesthesia is, of course, another drawback. The demands of such care require an expenditure of physical and emotional energy on the part of the physician, which is quite impossible for some men. It would be impractical for the average obstetrician and could be made possible only by the limitation of practice to a relatively small number of patients.

The presence of the hypnotist for at least part of the time during labor is essential, especially in the more physically painful termination of the second stage, when the head is riding over the stretched perineum. It may be necessary to reinforce the hypnosis and to keep the nurses away from asking the patient, "Are you sure that you don't want a hypo?"

Hypnotic anesthesia is a highly individual problem and varies from patient to patient and even changes in the same patient under different circumstances. For this reason group-instruction would seem impractical. Concentrated attention can be given to only one subject at a time.

Another practical difficulty is that the patient has to be placed in a room where no other women are in various stages of labor. The moaning and crying of these patients may unnerve her.

Hypnosis should not be used in prepsychotic or neurotic individuals, as a psychosis may be precipitated. But psychotics are difficult, if not impossible, to hypnotize.

Some psychiatrists contend that hypnosis fosters

extreme dependency. This may be true but a strong bond of dependency exists in every doctor-patient relationship. This dependency, however, is only temporary and of no importance. The reason

with each contraction, thereby facilitating and shortening the completion of the expulsive stage.

Reynolds, Harris and Kaiser³ could prove by tokodynamometry, a method to measure the force

Fig. 1. (Top) This diagram was taken when the cervix was dilated for a finger tip and the patient was not asleep. The contractions are irregular and the profile is uneven. (Bottom) One-half hour later, cervix dilated five centimeters at start, ten centimeters at end of record. Note change in profile as deep sleep was induced and when patient was awake. (From M. Rodriguez Lopez, S. R. M. Reynolds and R. Caldeyro Barcia: Arch. Ginec. Montevideo, 9:16, 1950.)

for the dependency can be worked through and dissolved through post-hypnotic suggestion.

The delicacy one must apply in dealing with hypnosis is another objection to its use. This points up the fact that until its value is more fully understood and accepted, it is a method best accepted by the doctor at the patient's request. These objections, however, can be eradicated if patients understand that the physician is only trying to teach them to assume healthy attitudes and that there are no magic powers invested in him.

Advantages

The late Dr. Lee stated, "The only anesthesia that is without danger is hypnosis. I am irked when I see my colleagues neglect to avail themselves of this harmless and potent remedy."¹

The carefully prepared patient will look forward to her confinement with a feeling of joy and happiness instead of dread and fear and she will be most co-operative during labor. Abramson and Heron² proved that with hypnosis there is an average reduction of two hours in the first stage of labor. During the latter part of the second stage the patient can be directed to bear down

and character of uterine contractions in pregnancy and labor, that there is evidence of effective uterine action by hypnosis.

Case Report

A patient was hypnotized early in pregnancy for painless delivery. When the labor began she experienced no pain but felt uterine activity. After two hours a record of uterine activity was obtained, and the two fundal areas were found to be the most active parts of the uterus (Fig. 1).

The record of the activity obtained at this time is shown at the top records. One hour later it was found that the patient was having stronger contractions without pain and that the cervix was dilated to five centimeters. After twenty minutes a deeper hypnosis was induced. The uterine contractions became strikingly regular and strong. At the end of fifteen minutes the patient was awakened by the hypnotist. The profile of the contractions became irregular. There was still no pain. In ten minutes she was again allowed to sleep and the pattern of contractility reverted to regular, even rhythm, as before. These measurements prove objectively the influence of hypnosis on uterine contractions during labor.

With hypnosis there is absolutely no respiratory or circulatory depression in the mother or the fetus with resulting anoxia, asphyxia and cerebral

damage. It is especially indicated when dealing with the delivery of a premature baby. Furthermore, it is known that one maternal death in one-thousand deliveries is caused by anesthesia, according to R. Hingson.⁴

The principle cause of death before birth and in the first few weeks after birth is interference with oxygen. Anoxia is one of the great killers and deformers during pregnancy. It is now known that much feeble-mindedness is directly due to lack of oxygen during the actual birth process and to heavy doses of drugs. It is also known that prolonged labor and abnormally prolonged contractions of the uterus at the time of birth are two ways in which babies are made anoxic. One factor which can prolong labor and uterine contractions is improper use of painkilling drugs and anesthetics during childbirth.

All drugs given to relieve the mother's pain, with the exception of spinal, caudal or local anesthesia, cross the placental barrier and affect the baby to some degree. It has often been demonstrated by the psychoanalytic approach that such conditions as rigid cervix can be influenced by fear and possibly prolong labor.

Eastman's excellent paper, "Mount Everest in Utero,"⁵ gives us the best explanation about the oxygen condition of the fetus. The fetus exists in a continuous state of cyanosis; a fact that is not only documented by countless blood oxygen studies but is plainly apparent at any cesarean section.

A perhaps even greater tragedy than the actual death of a newborn baby is the birth of a baby whose brain never develops. The incidence of

this condition, cerebral palsy, is much higher than most obstetricians would probably suspect. Of three thousand deliveries about eighteen of the babies born will develop cerebral palsy. More recently opinion has veered toward the belief that the main etiologic factor is intrauterine anoxia, whether intrapartum or antepartum. The cerebrum is one of the first structures injured by anoxia.

As a result of certain drugs and anesthesia the already scant oxygen supply is sometimes reduced to levels which kill or injure untold numbers of infants. On the other hand, there is not the remotest possibility of physical danger to the mother or baby from any type of hypnosis.

Because the lay press has stressed these factors, we have noted that more of our patients are now expressing keen resentment over being "knocked out" by medications. Good obstetric practice must concern itself more with the preparation of the woman's mind and less with the administration of noxious drugs.

STAPHYLOCOCCUS INFECTION IN A NURSERY

(Continued from Page 232)

that most staphylococcal infections in the newborn age group are preventable,¹ and that the sources of these infections can be detected with the equipment and personnel available in a small private hospital. Our observations in this particular nursery the past 18 months have demonstrated to us the value of a team approach to the problem of newborn nursery epidemics. The key members of such a team would seem to be:

1. A nursing administrator who is able to main-

tain a perpetual training and inspection program in the obstetric and nursery units.

2. A hospital bacteriologist who practices epidemiology as well as diagnostic bacteriology.

3. A staff pediatrician who actively serves as the public health officer of the nursery.

Hypnosis in Obstetrics

MARY E. GIFFIN, M.D.
Rochester, Minnesota

THAT properly utilized hypnosis may offer ideal anesthesia is a proved fact. That it can be performed with a minimum of apparatus and expense is clear. That it does not cause respiratory or circulatory depression in mother or fetus is evident. These and many other advantages are frequently listed, all with the implication that hypnosis is not a "toxic" agent. I do not agree with this view.

Scope of Hypnosis

Hypnosis is a technique for the induction of sleep, which can be light or deep. In either state, pain is dissociated from awareness; the patient is completely relaxed and is subject to the orders of the hypnotist within the bounds of the patient's own conscience. The technique and the wonders of the interplay involved in such "animal magnetism" have been the secret and the potion of the ancients and the spiritualists. Not until 1841, however, was the psychologic character of the hypnotic state scientifically delineated. At that time, a skeptic, Sir James Braid, was induced to examine a mesmerized subject; starting with a definite contrary bias, he ended his observations by recording not only the validity of the phenomenon but the psychologic nature of the reaction.

Hypnosis, like psychoanalysis, is first and foremost a research tool; what is possible with either approach is remarkable and frequently awesome. Both offer a means of understanding the depths and the intricacies of human behavior but, as is true of many laboratory methods, they should be handled only by those with proper understanding of the subtleties involved. They are best untouched by those caught in wonder but unlearned in psychodynamics.

Hypnosis permits the quantitation of stimuli

The practical experience reflected in this paper was obtained elsewhere. To this date, hypnosis has not been used in the Section of Obstetrics and Gynecology at the Mayo Clinic.

From the Section of Psychiatry, Mayo Clinic and Mayo Foundation.

The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

and the reliving of an ancient experience. Under proper direction, it may become a form of therapy. The technique of hypnosis merely sets the stage; the direction, manner and interpretation of the hypnotist's suggestions, their meaning to the patient, and the transference phenomena that occur between patient and physician determine the total result of the hypnosis. By implication, successful relaxation during delivery may be only the most superficial and positive effect of the hypnosis.

Hypnosis permits ready acceptance of suggestions, both of a regressive and progressive nature. A patient may regress to an early stage of his life, during which regression he will speak, look and react in a fashion consistent with that age period. He will recall facts and emotions that he had consciously forgotten and that he may be told to remember or forget on awakening, at the discretion of the hypnotist. If hypnotized for purposes of progression, he may be prepared, as is true of the patient before delivery, for constructive and mature behavior in the future. However, the anxieties that will be perceived and the reaction that may occur even out of consciousness cannot be disregarded with safety. The preparations for a happy experience of labor always must be accompanied by the opportunity for ventilation of anxieties and fears.

Hypnotic Analgesia

Kroger and DeLee¹ have presented the many advantages and a few disadvantages of hypnosis as contrasted with other forms of analgesia (Table I).

Only persons who have knowledge of the psychodynamics of the unconscious should use the technique; I wish it were otherwise, for there are few enough such persons. However, psychiatrists gave up hypnosis in the early years for exactly the same reason that obstetricians ultimately might give it up, namely the experience of uncovering more than their knowledge could handle. Now that psychoanalysis has offered more definitive understanding of basic conflicts, hypnosis once

TABLE I. ADVANTAGES AND DISADVANTAGES OF HYPNOTIC ANALGESIA IN OBSTETRICS

Advantages

Technique is simple
 No apparatus is required
 It does not depress circulation
 It does not depress respiration
 It does not depress uterine contraction
 It raises resistance to fatigue
 Analgesic effect is easily controlled
 Pain is dissociated
 Loss of blood is decreased
 Recovery is smooth

Disadvantages

Some patients are not susceptible
 Requires knowledge of psychodynamics
 Later effects may be tragic
 Best done by psychiatrist
 Predelivery and postdelivery contact necessary

TABLE II. INDICATIONS FOR HYPNOSIS IN OBSTETRICS

Home delivery
 Previously unexamined patients
 Premature labor
 Cardiac decompensation
 Respiratory conditions
 Myasthenia gravis
 Uterine inertia
 Bleeding tendency
 Psychiatric conditions

again is being explored in the treatment of psychiatric conditions, for now the hypnotist can use hypnoanalysis and hypnotherapy and not merely open the lines of cleavage of the personality. With proper use of psychodynamics, the unconscious conflict can be carefully controlled and handled.

Barring fear caused by faulty education and with the elimination of women who have inadequate anatomic faculties, the pain of childbirth depends on such factors as the size of the baby, multiparity, previous conditioning to pain, the threshold of pain, suggestibility, the attitude toward the unborn child, the attitude toward the husband and security in the feminine role. The last five of these factors may be susceptible to hypnosis. The most important psychologic factors involved are those related to the security in the feminine role; this is dependent on the quality of kindredness with the patient's mother, which is a deep-seated, complicated relationship with untold ramifications. Suggestion may permit equanimity during labor but, unless accompanied by proper analysis of basic conflicts followed by helpful reintegration, it is potentially dangerous and may be reflected in the patient's decompensation or in that of the child.

Indications for Hypnotic Analgesia

In view of the perfection of other anesthetic techniques, it appears appropriate to use hypnosis only in selected problems of labor. Such conditions are summarized in Table II.

Frequently, the proponents of natural childbirth and hypnosis extol the virtues of wakening the patient so that she may enjoy the pain of labor, the first cry of the infant and even the presumed pleasure of expelling the placenta. These experiences are supposedly of importance in solidifying the mother-child relationship. Rarely

does one note emphasis on an area of much greater emotional meaning to both mother and child, namely the use of hypnosis in stimulation of lactation. With only a session or two, patients frequently can be given posthypnotic suggestions that make nursing possible. The nursing relationship is a highly satisfying experience for the mother, and one that is basic to the child.

Hypnosis in Hyperemesis Gravidarum

I am impressed with the value of hypnosis, meaning hypnoanalysis and hypnotherapy, in conditions such as hyperemesis gravidarum. This disturbance is accepted by most physicians as being related to some basic psychosomatic condition. For years obstetricians have accepted the role of suggestion in the apparent efficacy of therapeutic agents. Sir Arthur Hunt, from the turn of the century, accepted pernicious vomiting as a symptom of hysteria. As such, it represents the unconscious wish to reject the child, based on an infantile view of oral impregnation. Many children initially believe that babies lie in the stomach and that entry is via the mouth; jealousy of the pregnant mother frequently is expressed by oral incorporation of many objects, and such children fantasy that the mother may vomit that which lies in her stomach. The choice of symptom, namely vomiting, represents in these women the childish strain of personality that remains and determines the expression of the rejection wish. Frequently, of course, these women insist that they want the fetus; without realizing it, however, they have unconscious wishes and drives to the contrary. Since the rejection wishes are unconscious in nature and since, once the condition has developed, time is at a premium, hypnoanalysis and hypnotherapy offer the quickest and, if properly controlled, a safe method of obtaining the unconscious material on which interpretive reintegration may be possible. The cases reported by Kroger and DeLee¹ indicate the results that are possible; of their seventeen patients who had pernicious vomiting, fifteen were successfully treat-

ed, one aborted and one could not be hypnotized. If a patient cannot be hypnotized, it may be because of her exquisite need to maintain the defenses that protect her, even if inadequately; it is possible that a psychotic break might follow if continued attempts at hypnosis are made in such cases.

Hypnotherapy offers a quick and definitive form of treatment in hyperemesis. The dramatic symptomatic relief that may follow even a single session is empiric evidence of the power of the hypnotic tool. It can be equally effective in heartburn, simple vomiting and threatened abortion. The hypnotic technique should not be used only for analgesia. It can be used with benefit for control of various psychosomatic obstetric conditions.

Dangers of Hypnosis

The dangers of hypnosis develop when suggestions are made toward a single symptom; if hypnotic suggestion disregards conflicts in personality, subsequent psychologic decompensations occur. Papers on the subject of hypnosis as an anesthetic agent measure failure in terms of failure to induce relaxation. Rarely reported are the psychologic states of the mothers after delivery. Mandy and associates² reported the postdelivery courses of three mothers who underwent presumably successful natural childbirth. These women co-operated in the Read form of suggestive technique, which is not true hypnosis, although it is closely related to hypnosis. Within three years, one of these women had committed suicide, the marriage of one had terminated in divorce and the third was suffering from severe neurodermatitis. The significance of the hypnotic experience in these subsequent events can only be conjectural. It appears likely, however, that a

tenuous psychologic hold was present in these three women which may well have been important in stimulating them to submit to natural childbirth, that their dependence on the obstetrician in this setting permitted temporary obedience to suggestion but that overwhelming anxiety developed when the dependency relationship was terminated as the postpartum period passed. These are instances of reactions following a light suggestive state. The inherent dangers of a state of deep trance are much greater, because the patient is less able to test reality, and the transference relationship between physician and patient is highly significant, activating many unconscious conflicts.

For the sake of completeness, I would add a note of warning. Hypnosis never should be used in the treatment of pseudocyesis or postpartum psychosis. Such a practice has led only to dire results.

Summary

Hypnosis is an effective analgesic. It remains a potentially "toxic" agent, however, unless its use is controlled by psychodynamic principles. It should be considered as an adjunctive obstetric analgesic and may be the analgesic of choice in selected cases. It can be of exceptional value in the treatment of oligolactia, hyperemesis gravidarum, heartburn and threatened abortion. Its effectiveness is a reflection of its potential "toxicity" when ineptly handled.

INSURANCE FOR ATOMIC ENERGY WORKERS

Of the more than 150,000 people employed in atomic energy plants throughout the United States, at least 99.7 per cent are now considered as standard risks for life insurance, requiring no extra premium due to any atomic hazard, the Institute of Life Insurance reports.

A coding system has been set up for all workers in nuclear energy plants. Each job has a coding-number, giving the measure of risk applying to that job. The coding-number for a worker is then made available to any life insurance company which has received an application from that worker for insurance. A rating of persons in these occupations is thus made possible without reference to information classified for security reasons.

All but a few hundred of the 150,000 atomic workers

are now standard-rated, insofar as the atomic risk is concerned. The small percentage for whom an extra rate is required, includes areas of certain nuclear reactivity or special research. During the war, all atomic workers, then mystery men, if insured at all, were usually charged an extra premium, running as high as \$10 per \$1,000 of life insurance.

Safety controls have come rapidly in this infant "industry," evidenced by resurveys of accident rates in many of the plants. Both frequency and severity of accidents in nuclear energy plants have dropped to one-fifth or one-sixth of the rates of 1943. It has been found that "A"-plant workers today have accident frequency and severity rates well below those in the petroleum industry or the chemical industry, for example.

Clinical Experience with Metaraminol

in the Treatment of Shock

MAX H. WEIL, M.D.
Minneapolis, Minnesota

THE CLINICAL value of potent vasopressor agents in the treatment of shock has been widely recognized. This has led to their successful application and increasing use in various hypotensive states, particularly in shock related to myocardial infarction and shock due to overwhelming infections. This paper summarizes the results obtained with metaraminol* (aramine), an agent closely related to, but in our experience, more satisfactory than norepinephrine (levophed).

Hypotension most frequently results from loss of effective blood volume, which itself is caused by hemorrhage, pooling of blood in dilated vascular beds, or dehydration. Return of blood to the heart becomes inadequate, cardiac output is decreased, and the blood pressure falls. This leads to further pooling and to a further decrease in venous return and thus a vicious circle results. At the same time the fall in arterial pressure leads to a reduction in coronary blood flow which subsequently causes defective myocardial contractility and a still further decline in cardiac output. Indeed, two vicious circles are established and these reinforce each other (Fig. 1).

Vasopressor agents like norepinephrine and metaraminol are effective in the treatment of shock because they control these progressive changes. It is well known that these drugs elevate blood pressure by constricting arterioles, but their therapeutic value has been closely related to at least two additional effects. In studies with dogs, we¹ recently demonstrated that the shock produced by Gram-negative bacteria is caused initially by pooling of large quantities of blood in the portal venous system, and that administra-

tion of metaraminol promptly remedied this pooling, with consequent increase in venous return. The studies of Gazes and Cotten and their associates^{2,3} with norepinephrine and the studies

Fig. 1. Pattern of the circulatory failure which initiates and propagates shock.

of Sarnoff, Case and their co-workers^{4,5} with metaraminol indicated that the beneficial effects of these drugs also are due in part to direct action on the myocardium producing increased myocardial contractility.

The chemical structure of metaraminol closely resembles that of both epinephrine and norepinephrine (Fig. 2). However, the pharmacologic actions of metaraminol are primarily like those of norepinephrine; and cardiac acceleration, stimulation of the central nervous system, or depression of appetite are not observed after administration of metaraminol.

Norepinephrine has the unfortunate disadvantage of injuring tissue at the site of injection. Even the use of a polyethylene catheter advanced well into the vein does not offer assurance against tissue necrosis and thrombophlebitis. Deep ulceration which involves the skin and subcutaneous

* Supplied as metaraminol bitartrate ("aramine" bitartrate) by Merck Sharp & Dohme Research Laboratories, West Point, Pennsylvania.

tissues has been disturbingly common, and has required subsequent skin grafting and even amputation.^{6,7} Other undesirable features of norepinephrine include the transiency of its action,

Fig. 2. The chemical structures of epinephrine, norepinephrine and metaraminol.

which necessitates administration under constant nursing supervision, and the need of large quantities of fluid vehicle when this may be undesirable because of inadequate excretion of urine. Preliminary results with metaraminol suggested that with this drug these disadvantages could be overcome and the desired therapeutic actions of norepinephrine retained.

To evaluate metaraminol clinically we studied the effect of it on thirty-one normotensive volunteers.⁸ We found that injection of undiluted drug by the intravenous, intramuscular, or subcutaneous routes was effective and never caused local injury to tissue. On intravenous administration the pressor effect became manifest in one to two minutes, was maximal in five minutes, and persisted for twenty to twenty-five minutes. On intramuscular or subcutaneous administration, a pressor response became manifest after five to twelve minutes and maximal elevation occurred at approximately thirty minutes. The action of the intramuscular dose persisted for only fifty minutes, but the action of the subcutaneous dose continued ninety minutes. For this reason, the subcutaneous route was favored in the treatment of many patients.

Subsequent studies, already published, involved forty-two patients with profound shock of four or more hours' duration.⁹ In most cases the shock was associated with myocardial infarction or caused by overwhelming infection. Administra-

tion of metaraminol was followed by prompt elevation of blood pressure from an average level of 68 mm. of mercury systolic and 57 diastolic to 120 systolic and 76 diastolic in thirty-six of the patients. The blood pressure was well supported for four or more hours in thirty-two patients, and twenty-eight patients initially recovered from the shock state. Despite this recovery from shock by 66.6 per cent of the patients, only 38.1 per cent (sixteen of the forty-two) ultimately survived their underlying illnesses—but this reflects the seriousness of their primary condition. The results with metaraminol are, as far as comparisons are possible, at least as satisfactory as those achieved with norepinephrine.¹⁰⁻¹²

Treatment with metaraminol often was started with a single intravenous injection of 3 to 15 mg. which produced a prompt elevation of blood pressure. When the peripheral veins were collapsed, the agent was injected directly into the femoral vein, whereupon the blood pressure was elevated and the peripheral veins usually became more normally distended. An intravenous infusion then could be started without difficulty, and a time-consuming and traumatic cutdown procedure thus avoided. In most patients the blood pressure was well maintained by doses of 3 to 25 mg. of metaraminol given subcutaneously and repeated every one-half to two hours. In patients who responded poorly, a continuous intravenous infusion of metaraminol in a dosage up to 200 mg. per liter of fluid was administered. After satisfactory control had been achieved, the subcutaneous route was preferred.

Metaraminol has since been employed by us in the treatment of more than 500 patients. The ease with which it can be given has encouraged its prompt use in shock. The value of this drug was particularly apparent among patients suffering from shock after myocardial infarction and among patients with bacteremia who required vasopressor support for many days. The use of subcutaneous injections at hourly intervals replaced the norepinephrine infusion. Skin necrosis, thrombophlebitis, or serious toxic side effects did not occur in this large group. The pressor effect of metaraminol has been remarkably easy to control and no decrease of response has followed its use for periods sometimes exceeding three weeks.

At times norepinephrine produces a pressor response when metaraminol fails to do so. However,

no patient of ours who clearly failed to respond to therapy with metaraminol ultimately survived in spite of prompt treatment with norepinephrine. A parallel observation was made recently by Stechel and his associates.¹³

In summary, metaraminol was found to be therapeutically effective, simple to administer without risk of injury to skin and subcutaneous tissues, and available for injection without additional fluid (thus especially suitable for patients with renal failure). These features make it a much more desirable drug than pressor amines previously available for the treatment of patients in shock.

Maternal Causes in the Etiology of Neonatal Pulmonary Disease

HENRY P. STAUB, M.D.
Minneapolis, Minnesota

THE PURPOSE of this study is to show, if possible, that there is a correlation between fetal distress and respiratory difficulty of the newborn infant. It is not uncommon that an abnormal delivery is followed by cyanosis, retractions, and grunting respirations of the newborn. This may be a coincidence, but if there is a causal relationship, such knowledge would be of importance in the management of labor and the treatment of the newborn infant.

Method of Study

We reviewed 1,000 infants born consecutively at Fairview Hospital in Minneapolis. A record was kept in the nursery listing each abnormal infant. The patient's chart was then reviewed and included in the study if the anomaly was obvious, such as prematurity, congenital malformation, or if the record indicated that the child had unquestionable pathology. Thus a short transitory attack of cyanosis or retractions was omitted, but if there was more than one definite symptom, or the child received treatment, or was diagnosed as having atelectasis by the physician, the case was included. We then carefully reviewed the birth record of each ill child; we checked mainly for Caesarean section, prolonged labor, precipitate delivery, rapid labor in primiparas, meconium stained amniotic fluid, or a drop in fetal heart rate. We noted whenever Pitocin was used to induce or hasten delivery, since we had seen some atelectatic babies after the use of the drug.

Results

Of the 1,000 newborn, fifteen died due to the usual causes of neonatal mortality (Table I). There were ten stillborn infants during this period. One hundred and four of the 1,000 newborns presented some major symptom of illness, or prematurity and recovered.

This paper was presented at the fall meeting of the Northwestern Pediatric Society in Bayport, Minnesota, Friday, Sept. 28, 1956.

We were particularly interested in the thirty-seven full-term babies and four of the larger premature babies who had respiratory symptoms. In this group were twenty-eight infants whose symp-

TABLE I. NEONATAL MORBIDITY AND MORTALITY OF 1,000 NEWBORNS

toms, physical findings, and x-rays (when available) were conclusive enough to allow a diagnosis of "pulmonary atelectasis." The other thirteen infants showed cyanosis, or some respiratory distress, such as grunting, excessive mucus, or difficulty in resuscitation, severe enough to warrant concern at the time. When we reviewed the birth record in each of these, we found in the majority of the cases some condition during the delivery which might have caused fetal distress.

TABLE II. POSSIBLE MATERNAL FACTORS IN 28 NEWBORNS WITH ATELECTASIS

Difficult delivery	1)	
Fetal distress	3)	5
Apparently normal delivery		3
		28

Of these twenty-eight newborns, two-thirds had either rapid labor or Pitocin, five had some sort of difficulty during delivery, three seemed normal. The precipitate labors were usually quite obvious. Under the rapid labors we included cases, such as a four-hour labor in a primipara, a six-hour fifty minutes labor in a thirty-eight-year-old primipara, an "unsterile delivery," and those cases in which the physician remarked on the rapidity of the

delivery. The cases with fetal distress showed meconium stained amniotic fluid, or a drop in fetal heart rate.

When we included the other thirteen cases with respiratory symptoms but not typical of "pulmonary atelectasis," the maternal picture did not materially change. (Table III)

Apparently normal delivery		7
		41

These so-called normal deliveries include three cases in which mother and infant might have been oversedated, but, since this is difficult to assess from the chart, they were classified as normal.

Discussion

Prolonged, difficult labor has long been recognized to be a cause of fetal distress. It seems that abnormally short labor may similarly traumatize the infant.¹ A severe prolonged uterine contraction often causes a drop in fetal heart rate. Such a contraction, forcing the head rapidly into or through a poorly dilated birth canal, may well cause cerebral edema. This may be the case in a precipitate labor or any abnormally fast labor. Pitocin can cause violent and prolonged uterine contractions. It may well be a safe drug for the mother, but the question must be raised whether it is safe for the fetus.

Pitocin is used quite often to induce or hasten labor. In 129 of the 1,000 infants studied, the mother had received the drug. In thirteen of the forty-one newborns with respiratory difficulties, or ten of the twenty-eight with atelectasis, Pitocin was used. This represents a third of all the patients with respiratory distress. It seems not unlikely that the use of Pitocin creates a similar situation and hazard to the newborn to that of rapid labor.

Are we justified in considering these cases of diverse pulmonary symptoms as one entity, the so-called "pulmonary atelectasis," and assume that it is likely to follow fetal distress? Our series, though admittedly small, seems to suggest this. Other conditions with respiratory symptoms—such as pulmonary hyaline membrane disease,² congen-

ital pneumonia, lung cysts, diaphragmatic hernia, tracheo-esophageal fistula, septicemia, major cardiac malformations—are either so rare in babies who survive or so obvious that they would have been diagnosed.

The initiation and maintenance of respiration are a function of the central nervous system. If a newborn does not start breathing, the difficulty cannot possibly be due to an obstruction or a pulmonary lesion; it must be central. Cerebral edema, or hemorrhage, often manifests itself in pulmonary symptoms.^{3,4} The respiratory symptoms of our cases were probably due to involvement of the central nervous system caused by fetal distress or more specifically fetal anoxia.

Conclusion

A newborn who had difficulty during the delivery is far more likely to develop respiratory difficulty than a child following a normal delivery. There is evidence that rapid labor, the so-called "tumultuous labor," and the use of Pitocin substantially contribute to neonatal respiratory disease.

This would lead us to the following suggestions in the management of labor and of the newborn:

1. Avoid drugs which might lead to precipitate labor or abnormal uterine contractions.
2. Discourage the traditional hanging the newborn by its feet and slapping it to initiate breathing.
3. Emphasize extreme gentleness, especially in handling the sick newborn.
4. Reevaluate the need for the customary Trendelenburg position for the baby with respiratory distress.
5. During the time when the child is recovering from the cerebral insult, provide oxygen as needed have the atmosphere well humidified, and give antibiotics to guard against pneumonia.

The Interpretation of Thyroid Function Tests in the Diagnosis of Thyroid Disease

ALVIN L. SCHULTZ, M.D.
Minneapolis, Minnesota

THE diagnosis of thyroid disease is still made primarily on clinical findings. Laboratory tests of thyroid function supplement and corroborate the impression of the clinician, but are never a substitute for careful and critical evaluation of the patient. Complete reliance cannot be placed on any single laboratory measure, and, in difficult diagnostic problem cases, a battery of thyroid function tests along with the clinical findings is usually necessary to arrive at a correct diagnosis.

The search for more sensitive and exact laboratory measures of thyroid function continues to interest many investigators in both basic and clinical endocrinology. It is estimated that in the past decade over 7800 papers on the thyroid gland have been published in the World medical literature.¹ Much of this impetus for research in thyroid disease has come with the availability of radioactive iodine, although the initial enthusiasm over radioiodine as a diagnostic tool has been tempered with greater experience. The present paper is a survey of the currently available tests of thyroid function and their value and interpretation in the diagnosis of thyroid disease.

Physiologic Considerations

Familiarity with the physiology of the thyroid gland is essential to an understanding of the laboratory measures of thyroid function and their interpretation and alteration in disease. For purposes of simplicity, thyroid physiology may be divided into the metabolism of iodine, the nature of thyroid hormone, and the degradation of thyroid hormone.

Iodine Metabolism.—Accumulation of iodide by the thyroid is an integral part of the synthesis of

thyroid hormone. Marine and Feiss² first demonstrated in perfusion experiments that thyroid was the only tissue that concentrated significant amounts of iodine. In autopsy studies on patients receiving radioiodine before death, it has been shown that significant quantities of iodine are found only in the thyroid and the urine.^{3,4} The thyroid to serum iodide ratio is normally about 50:1, and ratios of 500:1 may be found in hyperthyroidism and after thyrotropin administration.^{5,6} The average daily diet contains about 125 mcg. of iodine, and approximately 115 mcg. is excreted each day in the urine. The thyroid gland concentrates about 75 mcg. of iodine from the plasma daily, and roughly the same amount is secreted each day as thyroid hormone.^{1,7} These values indicate the high degree of efficiency and the minute quantities involved in the body's handling of iodine.

The thyroid continuously extracts its requirements of iodine from the plasma as iodide. The thyroid trapping mechanism has been studied by means of antithyroid drugs, such as propylthiouracil, which block thyroid hormone synthesis.^{8,11} It has been thus established that thyroid tissue will continue to concentrate iodide from the plasma, although the accumulated iodide cannot be synthesized into hormone. Trapped iodide in the blocked thyroid is freely exchangeable with iodide of plasma and can be displaced from the thyroid by thiocyanate, perchlorate, nitrate, and stable iodide. Despite the freely exchangeable character of thyroidal iodide, the concentration of iodide in the thyroid can be maintained at many times the plasma level. The exact mechanism of thyroidal iodide trapping is not known. The iodide trapping capacity of thyroid cells may be due to loose protein bonding between iodide and components of the thyroid cells, from which the iodide is readily dissociable.¹² In the unblocked gland, iodide is rapidly incorporated into amino acid-protein com-

From the Department of Medicine and Radioisotope Service, Veterans Administration Hospital and University of Minnesota, and the St. Louis Park Medical Center, Minneapolis, Minnesota.

Dr. Schultz is Clinical Assistant Professor in Medicine, University of Minnesota.

plexes and is no longer exchangeable. About 10 per cent of the thyroid iodine is in the form of iodide, the remainder being organically bound.

Figure 1 schematically illustrates the metabolic

Nature of Thyroid Hormone.—Until about ten years ago, it was generally accepted that only two iodinated compounds were synthesized by the thyroid, thyroxine, the active hormone, and

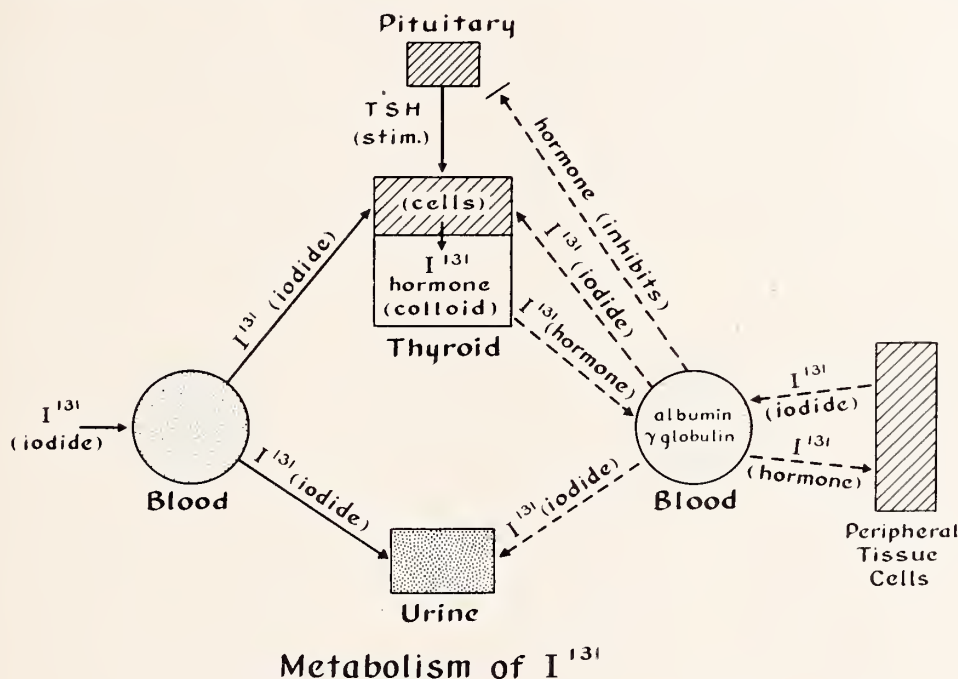

Fig. 1. The metabolism of iodine as indicated by radioactive iodine.

cycle of iodine as studied with radioiodine. The quantity of iodide extracted by the thyroid from the plasma varies with the functional state of the gland, being high in hyperthyroidism and low in myxedema. The kidneys are the only competitor for iodide; however, the renal iodide clearance rate remains approximately the same regardless of the functional state of the thyroid, averaging about 35 ml. plasma cleared of iodide per minute.¹³ Negligible amounts of iodide are excreted in sweat, saliva, and feces. Iodide is distributed and in equilibrium throughout the body fluids, constituting the "iodide pool." The plasma iodide level is maintained exogenously from food intake and endogenously by degradation of thyroid hormone with release of iodide.

Thyrotropin (TSH) released by the anterior pituitary has a stimulatory effect on the thyroid. Within two hours after administration of TSH there is an increase in serum thyroid hormone levels, and within eight hours there is an increased thyroid uptake of radioiodine.⁶ It is thought that release of TSH is inhibited by thyroid hormone, so that a reciprocal balance exists in the normal human, however, direct evidence for this is lacking.

3-5 di-iodotyrosine, its precursor, both compounds stored as thyroglobulin in the colloid of the thyroid follicles. It is now known that thyroglobulin contains at least two iodinated tyrosines and four iodinated thyronines, and other as yet unidentified iodinated amino acids.¹⁴ It has been established that there are at least three other biologically active iodinated compounds in plasma, in addition to thyroxine. The identification of 3,5,3'-tri-iodothyronine in plasma, thyroid, and other tissues by Gross and Pitt-Rivers¹⁵ has activated a complete re-evaluation of the action of thyroid hormone. 3,5,3'-tri-iodothyronine has been shown to have 3 to 5 times the biologic activity of thyroxine. 3,3'-di-iodothyronine and 3,3',5'-tri-iodothyronine, the other known active hormones in plasma, have approximately 80 per cent and 5 per cent the activity of thyroxine.

Evidence has now accumulated to indicate that the biologically active iodothyronines are synthesized from monoiodotyrosine and di-iodotyrosine. The compounds are then bound to protein, forming thyroglobulin, a glycoprotein of estimated 680,000 molecular weight. Thyroglobulin, which is non diffusible, is stored as colloid in the thyroid follicles. Through enzymic

proteolysis, the active hormones are released from thyroglobulin into the plasma, and the iodo-tyrosines remain in the thyroid where they are reutilized. Thyroglobulin as such is not found in plasma except in certain abnormal states such as radiation or surgical injury to the thyroid. The plasma iodine is composed of 10 to 20 per cent inorganic iodide, 70 per cent thyroxine, and the remainder, other iodinated thyronines including 3,5,3'tri-iodothyronine.^{15,16} The thyroid hormones circulate loosely bound to plasma proteins, mainly albumin and alpha globulin.

Degradation of Thyroid Hormone.—There is much speculation at present that tri-iodothyronine is the active tissue form of thyroxine. After the injection of I¹³¹ labeled thyroxine into athyreotic human subjects, labeled tri-iodothyronine appears in the plasma.¹⁷ It has been shown that thyroxine is deiodinated to tri-iodothyronine by rat kidney slices.¹⁸ Administered thyroxine has a peak biologic effect in four to five days and a metabolic half-life of about twelve days, whereas tri-iodothyronine is biologically active and completely metabolized within hours of administration. Myxedematous patients can be maintained in the euthyroid state with tri-iodothyronine. One factor in the more rapid action of tri-iodothyronine may be its looser binding to protein and thus its more rapid diffusion into tissues.¹⁹ There is no question that thyroxine and 3,5,3'tri-iodothyronine are both metabolically active hormones, but whether the latter and the other known active iodothyronines are derivatives of thyroxine cannot be answered at present. Inorganic iodide released into the plasma following the degradation of these compounds is utilized again in the iodine metabolic cycle for synthesis of thyroid hormone.

Thyroid Function Tests

Basal Metabolic Rate.—The rate of heat production by the body under basal conditions (relaxed and awake after a twelve-hour fast) has been termed the basal metabolic rate (BMR). Clinically the BMR is determined by measuring the rate of oxygen consumption from the lungs and indirectly calculating the rate of heat production. Under basal conditions, assuming the RQ (respiratory quotient) to be 0.82, the consumption of one liter of oxygen produces 4.825 calories. The hourly heat production per square meter of body surface can thus be calculated. The

TABLE I. FACTORS INFLUENCING BASAL METABOLIC RATE

1. Technical—O₂ leak, airway block, perforated ear drum
2. Food intake within 12 hours.
3. Smoking—raises BMR 5-10 per cent.
4. Poor rest, anxiety, irregular respiration.
5. Fever—10% rise per 1 degree temperature.
6. Age—8% decrease between age 30 and 60.
7. Voluntary alteration of respiration (—30 to +90).
8. Extra-thyroid disease: Lymphoma, acromegaly, heart failure, pulmonary disease, pheochromocytoma, polycythemia, hypertension, Parkinsonism, chorea, anorexia nervosa, starvation, obesity, Addison's disease.

average normal male under basal conditions produces 39.5 cal./sq. M./hr., and a female produces 36.5 cal./sq. M./hr. The BMR is expressed as the plus or minus per cent deviation from these normal standards.

The BMR reflects the rate of oxygen consumption of tissue cells, which is in part regulated by thyroid hormone. It is apparent that a great many other extra-thyroidal factors can effect pulmonary and tissue oxygen consumption. The more important of these factors are listed in Table I. Technical errors such as a loss of oxygen through a leak in the apparatus or a perforated ear drum, or anoxia produced by a faulty airway can markedly alter the BMR. The most common causes of alteration of the BMR are violations of the basal conditions. Food intake within twelve hours, lack of rest, anxiety, irregular respiration, smoking, and fever all cause elevation of the BMR. A healthy trained subject can so alter the position of his respiratory cage that BMR values from —30 per cent to +90 per cent may be produced at will, and with an apparently faultless spiogram tracing.¹ This experiment is simulated by the nervous, tense patient. Many diseases may alter the BMR unrelated to any thyroid function abnormality. The BMR cannot be interpreted accurately without knowledge of the conditions under which the test was performed and associated diseases of the patient.

Two variations of the standard BMR test have been used. An afternoon test has been studied in a small group of patients and apparently yields results comparable to the early morning test.¹ The patient has a light carbohydrate breakfast, does not smoke or eat after 11:00 a.m., and rests as much as possible until the BMR is determined at 1:00 p.m. Its only advantage is that of convenience. The somnolent BMR, performed with the patient under heavy barbiturate sedation has been used

to eliminate the effect of anxiety and nervous influences on the BMR.²⁰ This test is not without danger and results in no better separation of normal and abnormal thyroid function. Its use in an occasional extremely agitated patient may be warranted. However, other more reliable tests of thyroid function not influenced by nervous factors are available.

Approximately 75 per cent of normal persons will have BMR values between +10 and -10 per cent. To include 90 per cent of normal persons, the range of normal BMR must be extended to +20 to -20 per cent.

Serum Cholesterol.—It has been demonstrated that the rates of synthesis, destruction, and excretion of cholesterol are accelerated by thyroid hormone. Cholesterol synthesis is mainly in the liver. It is secreted by the liver directly into the blood and with the bile into the intestine where absorption into the blood occurs. Destruction and excretion of cholesterol is by the liver and intestine. Studies by Rosenman and associates²¹ indicate that the hyperthyroid state is associated with a markedly increased rate of hepatic synthesis, destruction and intestinal excretion of cholesterol, and the opposite occurs in hypothyroidism. The low serum cholesterol in hyperthyroidism is then presumably due to a relatively greater increase in the rate of destruction, and excretion of cholesterol as compared to the increase in the rate of hepatic synthesis. The hypercholesterolemia of myxedema is due to a relatively greater decrease in the rate of destruction and excretion. Myxedema is associated with hyperlipemia rather than just hypercholesterolemia. Free and esterified cholesterol, and phospholipids are increased, but neutral fat in the serum is not elevated.²²

Creatine Tolerance.—Ninety-eight per cent of the 120 gm. of creatine in the body is found in muscles, mainly as phosphocreatine. Creatinine is a product of creatine metabolism, excreted almost entirely in the urine. Creatine is usually not found in the urine of normal adult men, but is occasionally present in the urine of normal women. Creatine is almost always present in the urine of pregnant women, and children before puberty. Creatinuria may occur also in both sexes associated with high protein intake, starvation, carbo-

hydrate deprivation, severe diabetes, cachexia, poliomyelitis and certain muscular dystrophies.

Spontaneous creatinuria occurs in most patients with hyperthyroidism.^{23,24} An increased creatine tolerance has been noted in myxedema,²³ and the normal creatinuria of childhood may not occur in cretins. A decreased urinary output of creatinine is usually associated with the creatinuria of hyperthyroidism. Creatinuria in hyperthyroidism is probably due to the decreased capacity of damaged muscles to withdraw from the blood the creatine constantly formed in the body, and incorporate it into its creatine and phosphocreatine stores. As a result the blood creatine level exceeds the resorptive capacity of the kidney for creatine, and creatine appears in the urine. The decreased output of creatinine is due to the depletion of muscle creatine stores.

Shorr and associates²⁴ have devised a creatine tolerance test for the diagnosis of hyperthyroidism. The patient is placed on a creatine-creatinine free diet, and on the second day a twenty-four-hour urine specimen is analyzed for creatine and creatinine. On the third day 1.32 gm. creatine hydrate in 180 ml. water is administered orally, and a twenty-four-hour urine specimen again collected, and analyzed for creatine and creatinine. Normal persons retain 70 per cent of the administered creatine, hyperthyroid patients retain less. The creatine index, which is the ratio of twenty-four-hour urinary creatinine excretion in mg. to the body weight in kgm., is also lowered in hyperthyroidism. The index is twenty to twenty-eight in normal men and fourteen to twenty in normal women. Administration of iodine, even in small quantities, will abolish creatinuria, restore a normal creatine tolerance test, and eventually return the creatinine index to normal.²⁴

Serum Chemical Protein-bound Iodine.—As discussed earlier, thyroid hormone circulates loosely bound to the serum proteins, and can be measured in the blood as protein-bound iodine. The serum chemical protein-bound iodine (PBI) can be determined by distillation or alkalinicineration methods.²⁵ The techniques in general involve the precipitation of the serum proteins, digestion of the organic material and conversion of the iodine to an oxidized form, distillation or extraction of the iodine, and finally measurement of the iodine as iodide after reduction. The amount of iodide present is determined colori-

metrically by its catalytic effect on the rate of conversion of ceric sulfate (yellow) to cerous sulfate (colorless). The quantities of iodine involved are minute and great care must be taken in all phases of the determination to avoid losses or contamination with iodine. Much of the lack of confidence of many clinicians in this test can be attributed to attempts to interpret results obtained by careless technicians. Carefully performed, the serum PBI determination is a sensitive and useful measurement of thyroid function.

The normal range of serum PBI is 3 to 8 mcg. per cent. In a study of 404 normal men, 90 per cent had values between 4 and 7 mcg. per cent, 0.5 per cent had values below 3 mcg. per cent and 7 per cent had values above 8 mcg. per cent.²⁶ The mean value for a group of fifty euthyroid subjects was 5.4 mcg. per cent.²⁷ The serum PBI is frequently moderately elevated during pregnancy, gradually returning to normal after delivery.^{28,29} There is some decrease in the PBI with age.²⁶ High values have been reported to occur early in the course of infectious hepatitis.³⁰ Low PBI values occur in the nephrotic syndrome, hepatic cirrhosis, and starvation. Administration of iodine containing x-ray contrast material, iodides and thyroid extract produce elevation of the PBI. The rate at which these compounds are metabolized and excreted determines the time necessary before the test is again reliable. This will be discussed further in the section on radioiodine. Administration of tri-iodothyronine does not elevate the PBI. Exogenous and endogenous thyroid hormone are not differentiated by the methods. Mercurial diuretics will produce falsely low PBI values if acid-ash distillation methods are used, since iodine will be precipitated by the mercury during digestion and will not be distilled over and measured.³¹ The effect of mercurial diuretics on the PBI is usually dissipated within twenty-four to forty-eight hours.

Radioiodine Tests.—Radioactive iodine is chemically and biologically interchangeable with stable iodine (I^{127}), their only difference being physical. Since radioiodine emits penetrating gamma and short range beta radiation, it is possible to trace and measure it through complicated systems and in organs, blood, and urine by means of sensitive radiation measuring devices. Although fourteen radioisotopes of iodine have

8. Plasma conversion ratio at 24 hours Protein-bound I^{131}	× 100
Total plasma I^{131}	
9. Neck to thigh ratio	

been identified, only one, I^{131} , is in general use in clinical medicine, primarily because of its favorable decay rate (half-life eight days). I^{131} is usually administered carrier free, so that one millicurie of I^{131} is equivalent to only 0.008 mcg. of stable iodine. Thus I^{131} can be utilized as a test indicator of I^{127} metabolism without producing any pharmacologic effect. With scintillation radiation counters, tracer doses as small as one microcurie can be used and significant irradiation does not occur.

Radioiodine tests basically all measure either the rate of thyroid I^{131} accumulation, or the rate of appearance of administered I^{131} in the urine or the plasma. A variety of tests have been tried and discarded as insensitive or too complicated, and the thyroid I^{131} uptake has become the most generally used test. The various tests that have been proposed are listed in Table II. Oral tracer doses have been satisfactory for clinical use. The urinary excretion of I^{131} during the first twenty-four or forty-eight hours after a tracer dose was the first test widely used. It is a fairly accurate measure of thyroid function, since the urinary I^{131} excretion is inversely related to the uptake of I^{131} by the thyroid. Euthyroid persons excrete about 65 per cent of an administered I^{131} dose in twenty-four hours on the average, and seldom excrete less than 40 per cent. Hyperthyroid subjects usually excrete less than 30 per cent. Hypothyroid and euthyroid individuals overlap considerably in urinary I^{131} excretion and the test is less reliable. A delayed excretion of I^{131} between twenty-four and forty-eight hours occurs in

hypothyroidism and better separation of hypothyroid and normal persons is possible.³² Errors in collection of urine and unreliability of the test in the face of renal insufficiency and congestive

Fig. 2. Thyroid uptake of I^{131} at serial time intervals after an oral tracer dose.

heart failure has resulted in the replacement of this test by the direct measurement of thyroid I^{131} uptake.

Thyroid I^{131} uptake is the simplest of the radioiodine tests. At a variable time interval after an oral I^{131} tracer dose, usually twenty-four hours, the quantity of I^{131} accumulated by the thyroid gland is measured directly by means of an externally placed radiation counter, and the result expressed as the per cent of the administered dose taken up by the gland. The normally functioning thyroid will take up 15 to 50 per cent of the dose in twenty-four hours. In hyperthyroidism more than 50 per cent and in myxedema less than 15 per cent will be taken up. Studies of thyroid uptake within the first six hours after a tracer dose have demonstrated that good separation of normal and hyperthyroid subjects can be obtained.³³⁻³⁷ The upper limits of normal for thyroid uptake at one, two, and three hours after an oral tracer dose is 15, 20 and 25 per cent, respectively,³⁷ and at six hours is 25 per cent.³⁶ Curves of thyroid I^{131} uptake at various time intervals are shown in Figure 2, and indicate the effective separation of hyperthyroid, euthyroid, and hypothyroid groups.

In general, thyroid uptake is free of patient

induced errors; however, many drugs commonly used as medications or x-ray contrast materials, and certain non thyroid disease states will affect thyroid uptake and make the test unreliable. Iodides, in Lugol's solution, cough mixtures, and vitamin-mineral preparations, will depress thyroid uptake for seven to twenty-one days. Iodine-containing x-ray media for cholecystograms will depress thyroid uptake for three to six months, pyelograms for two to seven days, and bronchograms a year or more. The more recently available water soluble contrast materials used in pyelography and bronchography may depress uptake for only a few weeks or not at all. Iodized table salt does not affect uptake. The time necessary for the administered iodine to be metabolized and excreted determines how long the uptake will be affected. The length of time is considerably shortened in hyperthyroidism because of the greatly accelerated rate of iodine turn-over. The degree of uptake depression by antithyroid drugs, such as propylthiouracil, is related to the dosage administered. In hyperthyroidism, the uptake will return to the pretreatment level within seven days after the drug is discontinued.³⁸ While there is a measurable blood level of thiocyanate, the uptake will be depressed, but as the level falls, the uptake may rise into the hyperthyroid range as the hyperplastic iodine-poor gland soaks up iodine. This is the only drug which will produce an increased thyroid uptake. Butazolidin, PAS, ACTH, and cortisone all depress thyroid uptake for variable periods of time. Thyroid extract, thyroxine, and tri-iodothyronine depress thyroid uptake through inhibition of pituitary thyrotropin release. Usually thirty days is sufficient for recovery of uptake. A period of relative thyroid insufficiency follows thyroid hormone administration and moderate clinical hypothyroidism may occur lasting one to two months. The TSH test, which will be described later, can be used to differentiate primary myxedema and drug induced uptake depression, since the drug depressed gland can be stimulated to increase uptake. Iodine starvation, renal insufficiency, congestive heart failure, and large nontoxic goiters may be associated with moderate, but rarely marked elevation of thyroid uptake.

Many other methods for evaluation of thyroid function with I^{131} have been reported, but are more complicated, open to more error, and in general offer no advantage over thyroid uptake.

Thyroid I^{131} clearance, initially considered to be a more sensitive measure, has been shown to be no more effective than the simpler three or six-hour thyroid uptake.³⁶⁻³⁷ The rate of thyroid uptake and the thyroid accumulation gradient have been generally discarded for clinical use. The plasma conversion ratio and the rate of appearance of protein-bound or butanol-extractable (thyroxine) I^{131} in the plasma are considerably more complicated and less discriminative measures than thyroid uptake. They are worthless in the diagnosis of hypothyroidism. The total plasma I^{131} has almost no diagnostic effectiveness. The thyroid I^{131} uptake is the simplest and most diagnostically effective radioiodine test, and in further discussion of the thyroid function tests will be considered as representative of the radioiodine tests in general.

Interpretation of Thyroid Function Tests

Hyperthyroidism.—Many studies comparing the BMR and thyroid I^{131} uptake in the diagnosis of hyperthyroidism have been reported.^{7,32,36,40-42} It may be generalized that the thyroid uptake will be elevated in over 90 per cent of hyperthyroid subjects and the BMR in only 70 per cent. In a study of sixty-six hyperthyroid patients, almost all of whom had moderate or severe and only a few mild thyrotoxicosis, the BMR was +20 per cent or higher in 85 per cent.⁴⁰ However, 10 per cent of the patients had BMR values below +15 per cent and 8 per cent were below +10 per cent. Eighty-six per cent had twenty-four-hour thyroid I^{131} uptake values above 60 per cent, and in no case was the uptake below 50 per cent. The serum PBI was 9 mcg. per cent or more in the thirty-one patients tested. The serum cholesterol, although below 125 mg. per cent in 20 per cent, could not be considered of diagnostic value in individual patients. In a very comprehensive study of severe and borderline hyperthyroid patients, Skanse³² found the I^{131} tests abnormal in 98 per cent, the serum PBI in 93 per cent, and the BMR in only 78 per cent. In the cases of borderline hyperthyroidism, which were clinically difficult to diagnose, the I^{131} tests were abnormal in 95 per cent, the serum PBI in 86 per cent and the BMR in only 51 per cent. In a study of the discriminative effectiveness of the thyroid function tests in borderline hyperthyroidism, it was found that the thyroid I^{131} uptake most effectively separated euthyroid and hyperthyroid individuals

and the serum PBI was four-fifths and the BMR one-fifth as effective.⁴³ A weighted combination of the tests was only slightly more effective than the thyroid uptake alone. It is uncommon to find the thyroid uptake below 50 per cent in hyperthyroidism, although probably 5 to 10 per cent overlap between euthyroid and hyperthyroid subjects will occur in the range of 45 to 50 per cent uptake, and this range must be considered as borderline abnormal. Similarly, it is uncommon to find the serum PBI below 8 mcg. per cent in hyperthyroidism, however, the zone of 7 to 8 mcg. per cent must be considered borderline. Thyroid uptake at three hours after the tracer dose is more effective, both as to degree of separation and the amount of overlap, than uptake at twenty-four hours in hyperthyroidism.³⁷ Frequency distribution plots for thyroid uptake at one-half, one, two, three, and twenty-four hours in euthyroid and hyperthyroid subjects are shown in Figure 3. The more effective separation of the means for the two groups with uptake within three hours is particularly apparent in the plots.

The thyroid uptake is below 50 per cent more often in toxic nodular goiter than in diffuse toxic goiter, and occasionally when toxic nodular goiter is treated with iodine, the uptake may be markedly depressed for months despite continuing thyrotoxicosis. Following treatment of hyperthyroidism with radioiodine, the thyroid uptake is still a reliable, sensitive measure of the state of thyroid function.⁴⁰ In hyperthyroidism induced by thyroid hormone ingestion (thyrotoxicosis factitia), the BMR and serum PBI are elevated; however, the thyroid uptake is markedly depressed to myxedema levels.

Myxedema, Primary and Secondary.—The BMR is almost invariably below —20 per cent and usually below —30 per cent in frank myxedema. In milder degrees of hypothyroidism the BMR is more frequently in the low normal range. In frank clinical myxedema the thyroid I^{131} uptake at twenty-four hours is usually below 10 per cent and almost always below 15 per cent. Occasionally cases of undoubted myxedema are seen with uptakes between 15 to 20 per cent. It is very uncommon to find an uptake above 20 per cent in overt myxedema. Thyroid uptake within the first three hours after a tracer dose is much less effective than a twenty-four-hour uptake in the diagnosis of hypothyroidism. In

general, the BMR and thyroid I^{131} uptake are of equal effectiveness in the diagnosis of myxedema. The serum PBI, carefully performed, is a very

thyroidism cannot be answered. Unfortunately in milder degrees of hypothyroidism as in mild hyperthyroidism, all the thyroid function tests are

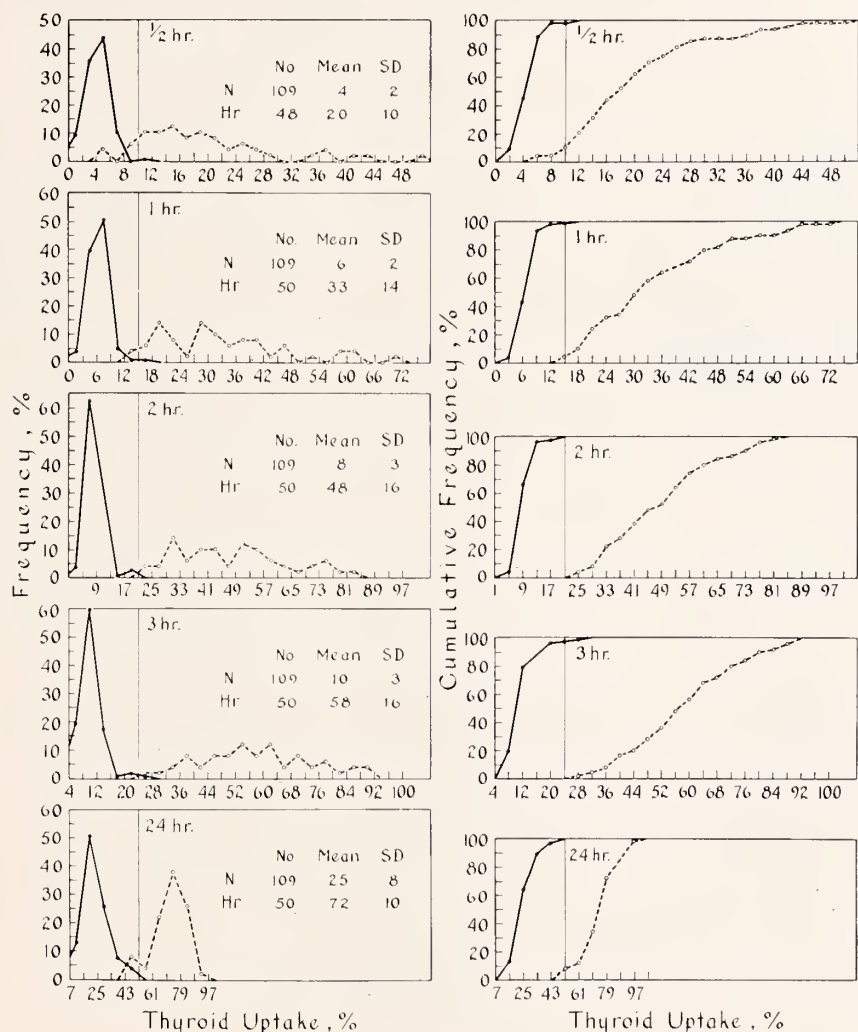

Fig. 3. Frequency distribution of thyroid I^{131} uptake at one-half, one, two, three and twenty-four hours after the tracer dose in euthyroid (N) and hyperthyroid (Hr) subjects. Solid lines indicate euthyroid, and broken line hyperthyroid.

sensitive measure of myxedema. Whereas in hyperthyroidism, the serum cholesterol is of little value in individual cases, in primary myxedema it usually is a valuable diagnostic aid. It is a particularly useful means of following the progress of a hypothyroid patient under treatment. The increase in serum cholesterol after treatment of hyperthyroidism with I^{131} , particularly in those patients who became hypothyroid is illustrated in Figure 4. In so-called hypometabolism without hypothyroidism the BMR is low and the thyroid uptake, serum PBI, and cholesterol are normal. The exact nature of this disorder awaits clarification, and whether it is a form of mild hypo-

frequently borderline and an absolute diagnosis is difficult to establish. The diagnosis of myxedema secondary to anterior pituitary failure is less effectively accomplished by thyroid function tests. The BMR and thyroid uptake are often less markedly depressed than in primary myxedema, and the serum PBI is commonly in the low normal range. The serum cholesterol does not become elevated in secondary myxedema. The differentiation of primary and secondary myxedema can be accomplished by means of the thyrotropin (TSH) test.⁴⁴⁻⁴⁷ A baseline thyroid I^{131} uptake is performed, following which 10 U.S.P. units of TSH is administered.

Twenty-four hours later the thyroid uptake is again determined. In primary myxedema no significant increase in uptake is elicited, whereas in normal persons and patients with secondary

response, and rarely, when irreversible atrophy of the thyroid has occurred, despite repeated stimulation with TSH, no response occurs. The TSH test does not distinguish a normal euthyroid sub-

Fig. 4. Changes in serum cholesterol after I¹³¹ treatment of hyperthyroidism in patients who failed to respond, had a satisfactory remission, or became myxedematous.

Fig. 5. The effect of thiocyanate on the accumulated I¹³¹ in the thyroid gland of a goitrous cretin.

myxedema, the uptake rises markedly. In some cases of long standing pituitary failure, two or three doses of TSH are necessary to obtain a

ject from a patient with secondary myxedema, since in both the uptake increases with TSH stimulation. The administration of thyroid hor-

none with resulting depression of uptake does not interfere with response to TSH stimulation.

Subacute Diffuse Thyroiditis.—The thyroid I^{131} uptake is markedly depressed during the active

indicating the iodine was still in the form of iodide and thyroid hormone was not being synthesized.

Benign Thyroid Nodules and Thyroid Carcinoma.—In nontoxic thyroid nodules, the tests of

Fig. 6. Scanogram of a benign diffuse toxic goiter.

phase of this disorder. During recovery the uptake gradually rises, although three to six months may be required for the uptake to return to normal. During the acute febrile stage, the BMR and serum PBI are commonly moderately elevated, and a clinical differentiation between thyroiditis and hyperthyroidism may be difficult. The finding of a very low thyroid uptake thus becomes very helpful. The low thyroid uptake of subacute thyroiditis does not rise with TSH stimulation.

Chronic Thyroiditis.—In chronic thyroiditis without myxedema, the tests of thyroid function are usually normal. A recent study of patients with chronic thyroiditis of the Hashimoto type indicated that the majority of these patients show laboratory evidence of primary thyroid failure, as reflected by low values for BMR and thyroid uptake, elevated serum cholesterol values, and decreased responses to TSH, although only a few have significant clinical myxedema.⁴⁸ In some cases of chronic thyroiditis with associated myxedema, the thyroid uptake is markedly elevated into the hyperthyroid range, although the BMR and serum PBI are low.⁴⁹ This same dissociation between iodine trapping and thyroid hormone synthesis is found in goitrous cretins.⁵⁰⁻⁵² The curve of thyroid I^{131} uptake in a goitrous cretin is shown in Figure 5. The three-hour thyroid uptake was in the hyperthyroid range, although the serum PBI was very low. The accumulated thyroid I^{131} could be discharged by thiocyanate without increasing the serum PBI,

Fig. 7. Scanogram of a goiter containing a solitary large benign adenoma in the upper pole of the right lobe.

thyroid function are usually normal. There is no test available which will differentiate a benign thyroid adenoma from a thyroid carcinoma. Radiation scanning devices which make radioautographs of the thyroid gland (scanograms) and manual differential counting of the gland have been utilized in an attempt to diagnose thyroid carcinoma.⁵³ Nodules which concentrate I^{131} are classified as "hot" or "warm" depending on the degree of uptake. "Cold" nodules are those which do not concentrate significant amounts of I^{131} . Although the great majority of thyroid carcinomas are non functioning and are thus cold nodules, this is also true of many benign adenomas. Also, since a nodule may be surrounded by normal thyroid tissue, it may be non functioning yet give the impression of concentrating I^{131} .

Figure 6 is a scanogram of a diffuse toxic goiter. The two lobes of the gland are well outlined and the absence of nodularity is demonstrated. Figure 7 is a scanogram of a goiter with a single large nodule in the upper pole of the right lobe. This nodule would be classified as cold. It was removed surgically and was a benign adenoma. Although, when available, scanograms are of interest and of some assistance in forming an opinion as to the nature of a nodule, they must not be used as a basis for a decision not to operate when other indications for surgical removal are present.

Case Presentation

Duplication of the Alimentary Tract

Report of Case of Double Uterus, Vagina, Large Bowel and Anus

C. N. BARNARD, M.D.
Minneapolis, Minnesota

DOUBLE intestine has been reported in various animals such as the bird, cow and ox. In man, one of the earliest reports is that of double hindgut which appeared in the early eighteenth century "Ephemerides" of Leopoldine Academy published in Frankfurt, Germany 1712-1717). Since then various cases of duplication of different parts of the alimentary tract have been reported. Gray (1940)¹ was the first to report a case of duplication of the large intestine.

We recently examined and treated a negro girl six years of age with the symptoms of incontinence of feces since birth, which were found to be due to congenital abnormalities of the hindgut. The case is here reported because of the rarity of the condition and the simplicity of the treatment to remedy the distressing complaint.

Case Report

H. W., a six-year-old negro girl, was admitted to Groote Schuur Hospital* on April 28, 1955, with the complaint of incontinence of feces since birth. According to the hospital notes, she had been admitted previously at the age of eleven days with the symptoms of a partial large bowel obstruction which was thought to be due to a stenotic ectopic vaginal anus. This was dilated with complete relief of the symptoms.

On examination, the child was found to be well-nourished and of normal development for her age. There was some distention of the abdomen with masses of indentable feces palpable in the hypogastrium and both iliac fossae. Examination of the perineum revealed the absence of an anus in the normal position but feces was noticed to come from the vagina.

Under general anesthesia a more careful examination was made of the introitus (Fig. 1). It was found that the vagina was divided by a vertical septum along its

whole length and at the distal end of the posterior vaginal wall were two rectal orifices, right and left, through which fecal material escaped. On digital examination each of these openings led into a separate

Fig. 1. Photograph of the perineum, and introitus showing the ectopic vaginal ani and septum dividing the vagina.

rectum. The urethral orifice was single. Cystogram and pyelograms revealed no abnormality in the kidneys or urinary tract.

Attempts at salpingograms were unsuccessful.

After cleansing the bowel through both external openings to relieve the fecal impaction, a barium enema was done. The barium was introduced by means of a catheter in each rectum. This investigation confirmed the

*Cape Town, South Africa.

diagnosis of duplication of the rectum (Fig. 2) and also revealed duplication of the entire large intestine (Fig. 3).

An emergency laparotomy was performed eight hours

At operation no cause for the acute symptoms could be found; however, examination of the large intestine was accomplished (Figs. 4 and 5). The bowel was found to be normally rotated with fixation of the cecum

after the roentgenographic examination because the child developed severe abdominal pain with rigidity of the abdominal muscles. It was feared that the manipulation during the examination may have perforated the bowel.

in the right iliac fossa. There was a common mesentery for the double large intestine and it was clear from the position of the longitudinal bands that there were two segments from the cecum to the rectum. The ter-

minal ileum was single and only one appendix could be detected. The sigmoid was unusually redundant and a persisting remnant of the anterior mesentery was found fixing the lower half of the posterior wall of the bladder to the anterior abdominal wall. On examination of the pelvic contents a double uterus was found. Each uterus had a single tube, ovary and round ligament (Fig. 6). The abdominal wall was closed in layers without further surgical interference and the child made an uneventful recovery.

Two weeks later under general anesthesia the dividing septum in the distal four inches of the large bowel was excised thus creating a single channel and only one external orifice. The fecal stream was diverted from the posterior vaginal wall by cutting back with scissors from the ectopic anus towards and across the normal anal site. No sutures were inserted.²

The postoperative treatment consisted of dilating the new passage daily and preventing fecal impaction with aperients and enemas.

Two months after this operation, the wound in the posterior vaginal wall had healed and a single external orifice in the perineum functioned with full continence.

The child was discharged, after the mother was taught to dilate the newly formed rectal canal.

Discussion

Duplication of the alimentary tract is a term suggested by Gross et al (1952)³ to describe a group of malformations with a common embryologic derivation. Although terms more descriptive of the individual case, such as "enteric cyst," "ileum duplex," "gastric thoracic cyst" and many others have been used, confusion will be prevented by using the term "duplication."

Hollow structures with three main characteristics are included in this term, namely:

1. The wall contains a coat of smooth muscle which may consist of one, two or three layers of muscle fibers. This characteristic immediately differentiates duplications of the alimentary tract from lymphatic and chylous cysts.
2. The lumen is lined by alimentary mucous membrane (not necessarily corresponding to the particular level of the duplication).
3. They are usually attached to the parent viscus although cases have been described where the cystic structure was some distance away and attached by a mesentery.

In approximately 80 per cent of duplications, the lumen does not open into the parent viscus and a cystic structure with the above mentioned characteristic results containing the secretions of the mucous membrane lining the cavity. The character of this secretion may be altered by patho-

logic changes resulting from congestion or ulceration of the mucous membrane or infection of the cyst. Ulceration is especially prone to occur when gastric mucosa forms the lining. The acid secretion and enzymes of the gastric juice are responsible for the destruction of the lining.

In cases where the lumen opens into the parent viscus, the fluid contents intermingle. Peptic ulceration may then result in severe gastrointestinal bleeding. (Barrett, 1951,⁴ and Wooler, 1950⁵). With duplication of colon and rectum or rectum alone, an external opening may also be present and this anomaly will conduct the fecal stream.

About three quarters of duplications are connected with the small intestine, but the anomaly may be found anywhere from pharynx to rectum. In 150 cases collected by Lo Presti and his co-workers (1950),⁶ cited by Maingot, the distribution was as follows: tongue two, esophagus sixteen, stomach eight, small intestine 115; colon five, and rectum four. The sixty-eight cases from the Children's Hospital in Boston³ were distributed as follows: tongue one, thorax sixteen, stomach two, small intestine thirty-two, cecum and colon ten, and rectum three.

Until 1944, the diverticulum theory propounded by Lewis and Thyng (1909)⁷ was largely accepted. These workers frequently observed out-pocketings or diverticula in the fetal alimentary tract of certain animals. As a rule, these out-pouchings regress and disappear; their persistence may give a plausible explanation for duplications. Against this theory is the fact that the evaginations consist only of mucosa and serosa and occur mostly along the antimesenteric border of the gut. Duplications, on the other hand, always occur on the mesenteric border and have a muscle layer.

Separation of a group of cells from the primitive intestinal tube may possibly develop into a structure having all of the characteristics of a duplication; however, a more acceptable theory was published by Bremer (1944).⁸ He points out that at about the six weeks' stage of intrauterine development, the lumen of portions of the intestinal tract become completely occluded by a rapid proliferation of epithelial cells. When the lumen reforms by the formation and coalescence of vacuoles in the solid mass of cells, he suggests that a group of vacuoles may not become continuous with the lumen. This isolated portion of the primitive gut can be expected to form a hollow duplication

which has in its wall all the histologic elements of some part of the alimentary tract. Moreover, it is attached to the otherwise normal alimentary system.

Edwards⁹ believes that duplications result from an attempt at formation of a twin which occurs at a late stage and thus affects only a limited segment of the alimentary tract. In support of this theory is a case reported by Kratzer, Dixon and Bargaen (1927)¹⁰ of duplication of the entire colon and terminal ileum associated with parasitic twin.

In about 30 per cent of cases of duplication, other developmental anomalies are present. In the sixty-eight cases described by Gross, twenty-one had other congenital defects of which atresia of the ileum or esophagus, malrotation of the intestine, and anorectal malformation were most significant.

The case reported herein, although presenting the single symptom of fecal incontinence, had several congenital malformations. As an embryologic explanation of the case in question, it is suggested that the duplication of the entire large bowel resulted from a double recanalization of the bowel after the solid stage (Keith¹¹). The ectopic external openings resulted from incomplete migration of the hindgut dorsal to the cloaca and the failure of establishment of a connection with the perineum (Keith 1952¹²). The two lateral vaginas were the result of a failure of the fusion

of the Mullerian ducts. This failure of fusion was also responsible for the duplex uterus. (Keibel and Moll, 1912¹³ and McBride, 1930¹⁴).

Continuation Study

Management of Head Trauma in Children

LYLE A. FRENCH, M.D.
Minneapolis, Minnesota

Skull Fractures

EVIDENCE of craniocerebral trauma may be present in an infant at the time of birth. When it occurs at such an early age it is generally but often incorrectly attributed to the use of forceps. Depressed skull fractures of enormous size may be observed in newborns who have had no contact with forceps. These depressions usually result from moulding of the very thin calvarium during the passage through the birth canal. They may vary from a small dent, a centimeter or two in diameter, to a depression of the entire side of the calvarium. They may even be bilateral. These depressed fractures usually reduce themselves spontaneously within the first seven to ten days of life, but if they do not, surgical elevation is necessary to prevent damage from compression of the rapidly growing brain.

Skull fractures in infants can be likened to depressions in a ping-pong ball because of the malleability of the skull. They are seldom comminuted and it is unusual for the injury to lacerate the brain. In older children, after the calvarium has become more solidified, compound comminuted fractures are fairly common. When they occur, early elevation of the bone fragments and closure of any associated dural tear is mandatory. The initial surgery should be definitive. If it is not possible for the initial surgery to be definitive because of deeply placed fragments or location of fragments in areas where one might expect severe bleeding from the brain or dural sinuses, it is probably wise to shave the adjacent area, apply a sterile dressing, or pull the skin edges together with a few sutures and transfer the patient to the care of a neurosurgeon. Children with head injuries can generally be readily and safely transported in the back seat of an automobile. They tolerate transportation well even at a very early age.

From the Division of Neurosurgery, Department of Surgery, University of Minnesota Medical School, Minneapolis.

Presented at the Clinic for Continuation Study, University of Minnesota, April 7, 1956.

APRIL, 1957

Linear fractures are of relatively little significance unless the fracture line crosses the middle meningeal artery or a dural venous sinus. In these latter instances a child must be watched very closely for signs of extradural or subdural bleeding. The management otherwise is that of a closed head injury. Linear fractures often are associated with subgaleal hematomas. Palpation of the edge of the hematoma which is firm, and at the center which is soft due to liquification of the clot, gives the impression a depressed fracture exists. Radiographic examination may be necessary to differentiate them. Because of the thinness of the bone in infants and younger children, an extradural hematoma may automatically decompress itself by leakage of blood through the fracture line, especially if the fracture line is widened because of increased intracranial pressure. This, of course, produces a subgaleal hematoma which is generally of very little clinical significance, except that its development in this manner might have been life-saving. Occasionally a linear fracture is associated with lacerations of the meninges and cerebrospinal fluid may leak out into the subgaleal space. This cannot be differentiated from subgaleal blood except by aspiration or continued observation. If it is blood, discoloration of the overlying skin occurs in a few days so differentiation is apparent. Seldom do either of these conditions need special treatment. If there is evidence of abnormality on neurologic examination, surgical removal of any subdural blood or cerebrospinal fluid and closure of the dural laceration is necessary. Subgaleal fluid accumulations not associated with neurologic abnormalities seldom need be aspirated but, if this is necessary, extreme asepsis is advised because of the natural capabilities of these cavities to promote bacterial growth.

Closed Head Injuries

The best treatment of closed head injuries revolves around good common sense and judgment. There is no special panacea. The general prin-

ciples of maintaining an adequate airway and treating shock are followed. It is emphasized that whereas shock may be present, it is an unusual accompaniment of head injury and, if present, careful search for a cause other than the head injury is advised. Following this, routine skull roentgenograms should be taken. It is believed that any patient with a head injury of sufficient severity to produce unconsciousness always should have skull roentgenograms. Only too often a depressed fracture can be diagnosed only by roentgenography. Also the evidence of a linear fracture crossing the area of the middle meningeal artery or the venous dural sinus is a warning of possible development of an intracranial hematoma. Lumbar puncture is advised against because it is noncontributory to diagnosis or treatment. Repeated notation of vital signs, including state of consciousness is mandatory. Alterations in level of consciousness, vasomotor status, or development of localizing neurologic abnormalities may herald intracranial bleeding. Children with head injuries should be maintained in adequate hydration. It is unwise either to force fluids or to restrict them to a point of dehydration. Sedation is seldom necessary; if used, it should be in small doses and care should be taken not to screen mental dullness due to increased intracranial pressure. Chemotherapy is desirable. Ambulation should be started as soon as any abnormal neurologic signs have cleared and the child is relatively symptom-free.

Subdural Hematomas in Children

The problem of subdural hematomas in children is entirely different from that in adults. In the case of adults, there is usually a definite history of injury, following which the patient has pronounced neurologic signs and symptoms permitting one easily to recognize the diagnosis. The treatment is to make trephine holes in the calvarium and evacuate the hematoma, following which the patient generally gets along very well.

In children, however, there is seldom any history of injury. Approximately 90 per cent of hematomas occur in children less than six months of age. The usual history is that the mother had a difficult labor or that the child had some respiratory embarrassment immediately following delivery. The child then gets along seemingly well for several weeks or months, except that he is a nurs-

ing problem. He fails to take his feedings, he is more irritable than normal, and the mother may notice that the child's head is enlarging rapidly or that the anterior fontanelle is bulging. When the child is seen by the physician, he presents a problem which at first seems to be simply one of nutrition, but then it becomes evident that the circumference of the head is enlarged beyond normal and the anterior fontanelle may be tense. The diagnosis is established by aspirating the subdural space after inserting a needle through the lateral angle of the anterior fontanelle. Normally, only a few drops of cerebrospinal fluid are obtained with such an aspiration, but in case a hematoma is present ten or more cubic centimeters of xanthochromic fluid can be obtained. Simple aspiration of the hematoma will seldom result in a cure in children, because there is a membrane around the hematoma which acts osmotically. The hematoma recurs. In order to cure the hematoma it is necessary to turn down a craniotomy flap and remove the hematoma along with the encircling membrane. Usually these children are not in good enough physical condition when first seen to tolerate a craniotomy. In fact, bilateral craniotomies are generally necessary, because 80 per cent of hematomas in children are bilateral. Therefore, it has been the policy to aspirate the hematoma daily, first on one side and then on the other, thereby reducing increased intracranial pressure. When the pressure is reduced the child usually begins to take fluids, and additional fluids may be given intravenously or subcutaneously. After a period of a week to ten days, the baby's general condition is usually satisfactory for craniotomy. The second craniotomy is done about a week later.

The postoperative convalescence in these children is generally uneventful, and the eventual prognosis is excellent. The children seldom have any physical, neurologic or psychiatric disturbance as a result of the hematoma. The reason that it is so important to remove totally the bilateral hematoma is that a child's brain doubles in size the first three months of life and doubles again in the next six so that at the end of nine months it is approximately four times birth size. If the hematoma and encapsulating membrane are permitted to remain, the brain development is greatly inhibited so that convulsive seizures, cerebral spasticity, and mental deficiency may occur.

STAPHYLOCOCCUS AUREUS— “HOSPITAL STRAIN”

The rapidly accumulating knowledge of the almost universally endemic virulent staphylococci in our hospitals has become one of the most important topics in medicine. Led by Minnesota's Wesley W. Spink (see article in this issue), the research in this field has revealed facts and trends which must be known by all physicians.

Micrococcus pyogenes, variety *aureus*, *escherichia coli* and certain other normal Gram negative bacillary inhabitants of the intestinal tract have been found to undergo a mutation from antibiotic sensitive to resistant organism strains in patients with or without infections caused by these bacteria. Within a year of the introduction of each new antibiotic the bacterial flora of our hospital rooms, corridors and operating rooms, as well as the nasal passages, skin and apparel of physicians, nurses, patients, and other hospital personnel will reveal the shift from staphylococcus aureus specific antibiotic sensitivity to resistance. A given “hospital strain” frequently varies from that of another hospital primarily in the uses or restrictions of certain antibiotics. Although not generally agreed upon by authorities, certain of these “hospital strains” might well follow a widely proven law of increasing virulence with each successive passage through an inflammatory process. At least one can be sure that they are coagulase positive and virulent, are carried in the nasal passages and on the skin by 30 per cent or more of the people working near the patients and contaminate the skin and upper respiratory passages of new patients within a few hours or days of admission to hospitals. They cause minor to fatal and sporadic to epidemic infections in: the newborn (see article by Williams et al in this issue), the otherwise clean traumatic and surgical wounds, the lungs of the debilitated, the intestinal tracts, in burns and the blood streams as well as in any of the entire gamut of sites of infection which the staphylococcus is capable of causing.

Alert physicians may know, with laboratory aid within eighteen to forty-eight hours of the onset of a suspected staphylococcus infection, its nature and the antibiotics to which it remains sensitive.

The immediate and proper use of two or more of these agents with drainage and other supporting care where indicated will produce improvement and cures unless the infection is too far advanced.

Hospital staff committees have been established throughout the country to control this menace in their institutions. Their efforts in lessening the spread from sites of infection to bed clothing, to dust, to nasal passages and skins of new carriers, to new sites of infection by varied steps and routes have met with success. However, the permanency and omnipresence of this potential danger will be with us for a long time in the foreseeable future.

“SKIN THE SEAL”

We don't know how taciturn the average Eskimo is, but we are willing to recommend a lot of our more verbose colleagues a perusal of the *Eskimo Cook Book**. The recipes in it are the epitome of simple directness. For example, the one entitled Seal's Bare Feet, starts with this imperative, “Put the seal's bare feet into a cooking pan.” And carries on in similar vein for about three more unequivocal sentences to where you have a meal of seal's flippers. Another, for the preparation of Seal Head begins abruptly: “Skin the seal. . . .” No review of the literature; no long-winded assignment of tenuous previous credits; no rehash of inadequate explanations; no impacted mass of proper nouns; no geometric abstractions like informed circles, eternal triangles, or official quarters; no technical waffle (here, this bit of technical waffle: technical waffle is a lot of words that sound good, but don't say anything); no list of references—just “Skin the Seal.”

So much for simplicity; now for forthright expression of opinion. When the contributor of a recipe expresses himself about how all this strikes him, again no straddling of the fence; no ambiguity—just a declaration of how he feels about this

**Eskimo Cook Book*, prepared by the students of Shishmaref Day School at Shishmaref, Alaska, and published exclusively by the Alaska Crippled Children's Association, P. O. Box 912, Anchorage, Alaska. 60 cents post-paid.

dish. For example, after the recipe for Soured Seal Liver: "Most of the boys and girls don't like it, except the grown-ups and old people. I don't like it either."

H.G.M.

THE NEED FOR HOSPITALS AND RELATED FACILITIES IN MINNESOTA

Rehabilitation is the ideal aim of all medical care. Restoration to self-care may be the highest point of return for some, but for many, return to employment is attainable and is of the utmost importance. Our hospitals and related facilities have always been dedicated to patient service. However, the value of integrating the services of one institution with those of other institutions, the combination of which would give the patient the total range of services needed, has not always been recognized. We can no longer afford such separation of function. Nowhere is the inadequacy of old concepts more evident than in relation to chronic disease and to the varied ramifications of long-term illness. We have been prone to feel that nothing could be done for people with such problems. Now we must think in terms of the totality of services needed to halt deterioration and to restore and maintain these patients at the highest possible levels of health and social effectiveness.

Early diagnosis is the key to prevention in chronic illness. It provides detection at a time when available therapeutic weapons are most effective and protects the patient from the cost of continuing long-term care. Ambulatory diagnosis and treatment are less expensive and more convenient to the patient. Prepayment and insurance plans should be geared to encourage patients to procure such on an ambulatory basis rather than through hospital admission.

Recently, interest in nursing homes has increased tremendously. However, even today, in spite of the fact that some very good nursing homes are operating, the average person's concept of a nursing home is an end-of-the-road place for the aged and infirm. Studies of nursing homes have shown that the quality of patient care ranges from very good to very poor. Imagination and initiative in the development of nursing home facilities and services provides a real challenge. After the pa-

tient has received the maximum benefits of hospital care but continues to be in need of nursing care, a good nursing home can be an effective and economical answer. Greatly needed is the development of modern nursing homes in close relationship to hospitals. We must seek improved design, higher standards and the full co-operation of philanthropy, government and insurance in easing the financial burden of patients requiring long-term care.

The patient with a chronic disease who needs hospital treatment requires not only the usual range of services available in a general hospital, but additional services as well. Experts in the problem of chronic illness urge that chronic disease hospitals providing intensive rehabilitation services be constructed as units of general hospitals.

The complete, comprehensive rehabilitation center which provides an integrated program of medical, psychological, social and vocational evaluation and services under competent medical supervision, serves the total patient, not merely his physical disability. It is no longer accepted as adequate to teach a person merely how to manipulate an artificial leg. He must also have an understanding of how to deal with the emotional problems that arise from his crippling and he must be provided with a means of making a living.

The development and operation of all of the various types of needed care facilities requires careful long-range planning, considerable imagination, co-operation, integration and resourcefulness as well as the active support of all concerned. Every community needs a carefully developed plan for the care of the chronically ill, long-term patients which establishes an orderly integration between the health and welfare agencies. The following types of needed facilities should be available for local use, although not necessarily on a local basis in the case of every community:

1. Care in the home. Expanded programs in public health and visiting nursing services as well as homemaker's service will frequently enable persons to remain in their own homes. Most persons prefer care in familiar surroundings under the supervision of their personal physician.

2. Substitute homes such as boarding care homes, homes for the aged and foster homes.

3. Nursing home facilities for the patient whose

This is the third in a series of editorials on hospitals and related facilities in Minnesota.

main requirement is nursing care under regular medical supervision.

4. Hospital care for the patient who needs close medical supervision, intensive professional nursing care, or definitive medical, surgical or rehabilitative services.

Because of extreme personnel shortages in many of the fields of rehabilitation, some patients who would benefit from more intensive rehabilitation services could be transferred for short periods of time to certain facilities not as yet readily available throughout the entire state, including:

5. Chronic disease units of the larger general hospitals, and

6. Comprehensive rehabilitation centers.

While we join forces in our local communities to provide care and rehabilitation services, we need to recognize that many areas will need to plan with their neighboring communities for some of the services on a regional basis. The demand for certain types of services will be limited and the shortage of highly trained technical personnel will be with us for many years.

Although larger communities need the services of physicians especially trained in physical medicine and rehabilitation, many of these services can be given to the patient by other specialists in medicine or by the general practitioner. The misconception still prevails among some physicians who believe that they may refer a patient to a physical therapist, an occupational therapist, a brace man, or a vocational counselor without being familiar with the functions and limitations of such trained health workers and their requirement and need for medical guidance.

Society is rapidly becoming aware of the needs of the long-term patient. New developments are occurring rapidly, many of which are not too carefully planned. These growing pains and the associated frustrations can be overcome if we are aware not only of our strength but also of our weakness and of the areas in which improvement is possible and essential to the ultimate success of rehabilitation as it plays its vital role in the care of the long-term patient.

HELEN L. KNUDSEN, M.D.

MINNESOTA HUMAN GENETICS LEAGUE

The program of the Minnesota Human Genetics League is concerned with the qualitative and quantitative aspects of the population. Thoughtful people throughout the world are now accepting the related problems of the genetics and the numbers and distribution of peoples as the most fundamental ones that there are. It was not always so. The fact that many people are now seeing human biology as the crux of social changes comes through education by the press, radio and television. These distribution mechanisms obtain their data from conferences, research papers and interpretative material produced by organizations like the League.

In 1948, the League helped to sponsor a population conference on the University Campus. At that time, it was necessary to show the public that there was a world population problem. The League cosponsored a second population conference in late January, 1957, which had the ambitious goal of trying to define what an optimum population would be. Roughly how much food, clothing and shelter, leisure time and community resources, are needed per person to ensure a healthy progressive society?

A study initiated by the Dight Institute and the League on Huntington's chorea has led to unexpected successes. The project was started in a very modest way but attracted the attention and assistance of Dr. John S. Pearson, head of psychological services of the Department of Public Welfare of the State of Minnesota. When Dr. Pearson went to the Rochester State Hospital as the research psychologist, he interested the Superintendent and others there in the organization of a Genetics Research Program. The work started with the help of the Dight Institute and was expanded with the aid of a generous grant from the Hill Family Foundation. The program was centered around the Huntington's chorea work, now to be done on a statewide basis. A census of all choreic persons and their close relatives has been completed. A popular interpretive pamphlet about the disease written by Dr. Pearson is being used throughout the nation. The League financed the printing of the first 5000 copies of the pamphlet. Efforts to distinguish which half of the progeny of a choreic

Final editorial in a series of six on the work and accomplishments of the Minnesota Human Genetics League.

person will later develop the disease are being continued. Movies of patients before and after treatment with reserpine show a remarkable suppression of symptoms, which lasts for at least a few months. The understanding of the mechanism of the inheritance of the dominant gene for the disease which the relatives and early-stage patients have obtained has resulted in voluntary and unsolicited guarantees from some that they will refrain from reproduction and further spread of the gene responsible for this horrible disease. Even a few results of this sort are of great significance to the families involved, to the state and the country. A similar program is now flourishing in Michigan, and will no doubt be initiated in other states.

The research project which the League initiated and for which it assumes responsibility is a gigantic follow-up of a study made of the mentally deficient patients at the Faribault School and Colony. The patients there between 1911-1918 and their relatives were studied with geneological, psychological, and sociological techniques. The follow-up of the descendants of the patients and relatives using the same and newer methods has provided vast amounts of data. In many cases, the family group of relatives of the patient comprises over 500 individuals. Every one of the 300 family groups selected for study is different in its display of mental retardation. In those families where mental retardation continues down through the generations, there is an opportunity to make a future intensive study, using biochemical and other medical adjuncts, with the expectation that new diagnostic techniques, and perhaps some treatments, may be discovered which will lighten the load of the mentally retarded and their relatives in the future.

The mental retardation project has attracted wide attention. Sheldon and Elizabeth Reed reported on the progress of the work at the First International Congress of Human Genetics, which was held in August, 1956, in Copenhagen.

In addition to its research program, the League has contributed to general education by bringing world authorities to Minnesota where by public addresses, conferences, and radio broadcasts an awareness and some understanding of human genetics and population problems have been engendered. Dean Laurence H. Snyder, President of the American Association for the Advancement of Science, Lady Rama Rau of India, Philip

Levine, M.D., Edmund Farris, M.D., and many others have left their imprint upon you and me, and the people of Minnesota.

Thus as the Minnesota Human Genetics League completes its first decade of life, it can look forward to a highly challenging program befitting its greater maturity. What has been done is a very small beginning. The opportunity ahead is practically limitless in its potentialities for human good.

SHELDON C. REED

ALCOHOLISM IN INDUSTRY

As a layman with a long and intense interest in the problem of alcoholism, I am grateful for this opportunity to reach the physicians of Minnesota through their journal with regard to the problem of alcoholism in industry. It is hoped that in this and the editorials to follow it will be possible to provide a description of some of the problems that alcoholism presents to industry, some suggestions for meeting the problem, and finally, some suggestions on the physician's role in this problem as seen by a layman.

The fact that a series of editorials on alcoholism in industry should appear in this journal is significant in itself. Some of us who have been concerned about this problem for a number of years have often been impatient with physicians, the clergy, the law and industrial leaders for their failure to recognize alcoholism as one of their responsibilities. Objective reflection, however, will cause us to realize that progress in the field of alcoholism, while still too little and too slow, has in fact proceeded at a rapid rate.

The general acceptance of alcoholism as a health problem today is not a recent development or the result of a sudden awakening on the part of physicians and the public. It is rather the result of an evolution in the thought and actions of our society. Alcoholism has long been considered a moral problem, but it was not until it was also recognized as a medical problem that any real progress in the rehabilitation of its victims was possible.

It has been interesting to observe the growth of interest in alcoholism. Prior to 1935, when Alcoholics Anonymous was started, little was done to help the alcoholic person outside of some church groups and occasional well-advertised "cures." Today, thirty-one states and many cities have active

First in a series of articles on Alcoholism in Industry.

programs for the rehabilitation of the alcoholic, and others are considering the development of programs. Interest in alcoholism has snow-balled, and today this former "hidden sickness" is being cognized and discussed everywhere.

One major product of this evolution in thinking has been the interest recently shown by industry. Several years ago a public opinion poll was taken of top management to determine whether or not alcoholism constituted a problem in industry. The answers were uniformly negative. There was no problem. To anyone familiar with industry or with alcoholism, this should not be surprising. Top management is not always aware of employee health or emotional problems. This is particularly true with a condition such as alcoholism which is kept well hidden until the last stages. It was not until it was clearly demonstrated to management that a serious problem existed that was costing their concerns vast sums of money that any positive steps were taken to meet the problem.

It had always seemed a simple solution for management to discharge alcoholic employees. Management began to recognize the futility and waste of this procedure when it was pointed out that the average employee discharged for alcoholism had been with the company for over twenty years, and was often a highly skilled worker. Soon other factors became apparent. The alcoholic employee was losing more than eighteen days a year because of his illness in comparison with seven or eight days for other employees. Higher accident rates, greater waste and spoilage, and lowered production were other factors that became evident. The lowering of the morale of fellow employees is a factor that is impossible to estimate in dollar value but is nonetheless very real.

Although the physician's relationship to the problem of alcoholism in industry is usually an indirect one, it is nevertheless an extremely important one. Two general areas in which the physician can play a very important part are in the areas of treatment and education. It is on these points that I would like to expand in the editorials to follow.

PATRICK BUTLER, *Chairman
Minnesota Advisory Board
on Problems of Alcoholism*

IT PAYS TO BE NICE TO PEOPLE

Think of the successful people you know. Have you ever wondered how they got ahead? Lucky breaks—maybe. Better education—not all of them. Nine times out of ten it's because they found out that the way you treat others can make or break you, that it pays to be nice to people.

George Brown found this out. He works at the information desk in one of our power and light companies. He has more friends and knows more people than anyone else in the company. Everybody likes him. The company has received many letters telling of his courtesy and helpfulness.

One day while waiting in the lobby for a friend, I couldn't help noticing that most of the people who came in singled him out with a cheery hello, a friendly smile, a how-are-you-today or a how-are-you-doing—all for George. He certainly was getting his share of attention. Then, as he noticed a stranger trying to look in all directions at once, he quickly got up and walked over to him. He talked with him a few seconds.

You could see that the stranger was pleased. They walked over to the elevator and George spoke to the operator. The stranger was smiling now as the operator closed the doors.

When George turned around, he came over to where I was standing and said, "Someone to see Mr. Miller, I just wanted to be sure he got to the right place."

I couldn't hold back my curiosity any longer and asked, "George, how did you become so popular?" I had my own ideas, but I wanted to hear what he had to say.

"Well," he said, "a few years ago, I read in a paper about a man who was included in a will just because he smiled and was nice to people. I thought maybe it would happen to me. So I began treating people like human beings. It made me feel so good that I didn't care if I ever got a million dollars. You know, it pays to be nice to people."

Think it over. Don't you prefer to do your shopping and buy your newspaper at certain places, where people treat you in a friendly way? Wouldn't you sooner work with people who are pleasant and good natured? If people are friendly you like them. If you are friendly they like

Copyright 1954 by Prentice-Hall, Inc., New York, N. Y. Reprinted by permission of the publishers.

you. It's as simple as that. But since it's simple, don't we often take it for granted?

It's easy to overlook the fact that your job is a great deal more than materials, tools, and methods. It's also people. It's the fellow who works with you, the new man, the old-timer, or the fellow in the office across the hall. It's Joe, Jim, Susie, and all the rest with human feelings, dreams, likes, and dislikes.

Now I can almost hear someone say, "How about the grouch, the sourpuss, the gloom spreader and all the other characters that we run into every once in awhile?" That's an easy one.

Take Ed Smith down at the garage I patronize—a whale of a good mechanic, knows his business and gets the work out, but he's one of those fellows who would just as soon bite your head off as look at you. People stay away from him. With his ability he could be head of the Service Department, but people just don't like him. His treatment of others has boomeranged. To make sure that you are not another Ed Smith, don't overlook the power of friendliness.

Not long ago my friend Harvey Wilson's son, Dick, won a fine promotion simple because he made little extras in the treatment of others work for him. One of the boys from another department came in one day to straighten out some of the work he was getting. He was burned up and let go with both barrels.

Dick could have met him head on with more of the same kind of fireworks—but he didn't. He was as steady as an old sea dog in a storm. He had headed off trouble like this before. Dick listened, asked questions and showed that he was really interested. The smoke cleared and they talked the whole thing over.

When this fellow went back to his department, I heard Dick say, "Anytime anything like that comes up, let me know and we'll work it out." It wasn't long before his ability to get along with others was the talk of the grapevine. Other people were pulling for him. He had a following of boosters. His promotion to assistant department head was one of the most popular ever made in the Company.

His way of dealing with people paid off.

It doesn't take much sometimes to turn things in your favor. The greatest runner in the world isn't more than 5 per cent faster than scores of other runners. The best fighter may win by going just

another round and the greatest inventor by just one more try. Sometimes it takes so little change a minus into a plus. I know of no situation where this is more true than in your dealing with people. You'll find that opportunity is always looking for the person who has that little extensibility to get along with others.

It Doesn't Cost Anything

You don't have to be a millionaire to be nice to people. You can be extra nice and not have it affect your pocketbook one bit. It's free. Here are just a few ideas. You can think of many more.

Wear a Pleasant Face. If you want a better job to turn up, keep the corners of your mouth that way. The other fellow may be a bit grouchy from any number of things that bother us in a day's living and not give a friendly smile himself. Head off grouchiness by smiling before the other fellow has a chance to be grouchy. It's the face with the smile that wins.

Let people know you are glad to see them. Show it in the way you look and what you say. Let them see that twinkle of recognition. Take a tip from your dog, the friendliest greeter of all. He will wag his tail and almost wiggle himself apart to show how glad he is to see you.

If you really want to be especially nice to someone, listen to him with all your heart. My dentist office girl is the kind of person who just can't stop talking long enough to listen to anyone. Give her half a chance and she'll tell you all about her operation, pet peeve, or relatives. Did you ever stop to think, how wonderful it is that the good Lord gave each of us two ears and only one mouth?

How we all like attention! Say something about that special job, good idea or thoughtful favor. Say something about your neighbor's garden, fishing trip or hobbies. There are hundreds of things you can notice about people. Speak up. They'll think you're wonderful.

It's unbelievable but one would think that it's actually harder for some people to part with these acts of friendliness than to part with their money. It's the little things, the tremendous trifles, that get the farthest in the enjoyment of our everyday living. So often it's these things that tip the scale to just getting by or to outstanding success. Don't

neck these acts of friendliness at the door when you go to work. Take them along. Make them work for you.

Check Up On Yourself

There's a fellow over in our sales department, whom I'll call Ned Randall. Ned used to be considered a pretty good man, but something has happened to him. It's no fun being around him anymore. Because he has a what's-the-use-attitude, no one dares give him a break. He does just enough work to get by, and he can tell you just what's wrong with everybody else in the place. How many people do you know who are like Ned Randall, sulking, brooding, blaming others, thinking of quitting, working in low gear—getting nowhere? Stay out of this rut! One of the saddest things about a man in this rut is that he had no idea he was getting into it. Slowly but surely he drags himself down. Before he knows it he has become his own worst enemy.

One sure way to stay out of this rut is to take a good honest look at yourself. Check up on your weak points as well as your strong ones. Don't have anything out. See if you can face up to these.

Give the Boss a Break. Now just a minute, don't backfire at me! He's human too. Maybe he has some shortcomings, but don't we all? Remember, he's got to try to keep everyone satisfied—beginners, old-timers, gripers, good workers, poor workers. He has his troubles, too.

Roll Up Your Sleeves. Pitch in and do your job. You don't like to work with someone who isn't doing his share. There is no future in just getting by—you only cheat yourself. You miss out on the pride that comes from doing a good job, the respect we all have for a person who can really do his job well, and most of all, your chance to show what you can do.

Put something of yourself into your job. My neighbor Henry Sims, a foreman in one of the plants in town, says that he can always spot a coming top notcher by the extras he puts into his job. No one can tell you what this extra should be. You are entirely on your own. Maybe it's a better way to do something, extra friendliness, a little better job—it's up to you.

Be On the Beam. It's almost impossible to

enjoy your work if you aren't friendly with others on the job. We all spend a good share of our daily lives at some kind of work. Why not enjoy it? So don't knock the people who work with you—get to know them. The ability to get along with others will pay you the biggest dividends in the world.

It will pay you to watch these things as carefully and regularly as you wash your face and comb your hair. Pay less attention to the shortcomings of others. Look yourself over.

Make sure you are not standing in your own way.

Go Out of Your Way

"I tried to be nice, but do you know what he said to me?—If that happens again, I'm going to give someone just what he is looking for . . ."

We've all been in spots like this, but very often we give up too easily. We take a what's-the-use-attitude, pull down our flag and quit. The whole day has gone wrong. You have been snubbed—brushed off. So what? You're bound to have a few of them because some people have let themselves get so sour on others that they feel that anyone treating them like a human being is not to be trusted, or is trying to sell them something.

Bill Knowlton, the captain of our bowling team, likes to make this point. "I remember the good cookies my mother used to make. As a youngster I did just what came naturally. The ohs, the ahs, the mms and the great big smile worked wonders for me—two cookies, maybe even three or four. It pays to be nice to people. Time hasn't changed it one bit. It still does the trick."

Go out of your way, carry friendliness to others without waiting for them to come halfway. Stick your neck out. The other fellow may be shy too.

You don't have to be a gushing back-slapper either. People soon spot a counterfeiter in friendliness. And don't just reserve it for Christmas and birthdays—turning it off and on depending on the situation. Make a habit of it.

There is an old saying that goes, "The hardest part of making good is that you have to do it every day." Try out these friendly tips on everyone you meet, the boss, your fellow workers, your family, friends and neighbors. It doesn't cost anything, and it will do you more good than you ever expected.

Working together is not hard to understand

when two men are sawing a log—when nine are playing the favorite American game—when ten are taking orders from the quarterback. But in many other situations we lose sight of the fact that the success and pleasure in work comes from getting along with others on the job.

Give yourself a break. Don't short change yourself. You can have a lifetime of extra success and happiness—beginning right now.

VERNON C. JOHNSON

STUDENT FACULTY RELATIONS AT THE UNIVERSITY MEDICAL SCHOOL

Student faculty relationship are probably the main area of interest of the Medical Student Committee. To discuss the work of this group and leave this area out of the discussion would be a grave error. Student faculty relationships at Minnesota are not really terribly bad, but the point is that they could be, and we feel should be, better.

A poll of students and faculty taken in May, 1953, showed that more than 80 per cent of both faculty and students polled want more opportunity for informal contact between student and teacher. Thus, this is a problem to the faculty as well. However, it has not been an easy problem to tackle.

The genesis of the lack of good relations is obscure. Certainly some of it lies in the very bigness of the institution. It is indeed advantageous to be so close to the main campus of the University, but the University itself is concerned with the lack of school unity that is manifest on the entire campus. Medical students are looking forward to the day when they will have a separate graduation ceremony. We have been led to believe that such a day is coming. Perhaps this one step will add a necessary ingredient to a feeling of unity within the medical school.

The Medical Student Committee has considered a number of ways to improve student faculty relationships. An advisor system was considered but abandoned. Coffee hours for students and faculty members have been tried and seem to be quite successful. Some members of the committee met with the faculty on a student faculty relationships committee. This committee has drawn up its

recommendations, but they have not as yet been presented to the students.

Definite progress has been made to improve relations between faculty members and students. There is a need for continued improvement. The Medical Student Committee is actively working along these lines. Such a program should also add immeasurably to the as yet poorly developed school spirit at Minnesota.

RALPH B. SWANSON

REHABILITATION IN PULMONARY TUBERCULOSIS

Some Illustrative Results of Vocational Training

In the fall of 1954, Papworth made a preliminary survey of the results of the present training scheme introduced in 1948 as a result of agreement reached with the Ministry of Labour. There had been 665 admissions. They were in every stage of disease, the majority in Stage II (moderately advanced). Fourteen persons had died, six of them in the Papworth hospital; all fourteen had advanced (Stage III) disease, with positive sputum. In addition, fifty-two had been discharged as unfit for training. There were 273 still at the Settlement, sixty of them as colonists working in the industries, six as housewives in the village and the remainder at varying stages from rest in hospitals or hostels up to work from three to six hours per day. A total of 306 had left for open industry, and it is the known fate of these ex-patient workers that we shall now consider.

Of the total number, 186 had been admitted because of continuance or recurrence of positive sputum, in spite of hospital, clinic or domiciliary treatment. They had been unable to obtain or unable to retain employment. Once rendered sputum-negative during their stay with us, 102 patients had remained negative up to the date of discharge, while a further forty had again reverted to positive sputum at some stage of residence but had left sputum-negative. This means that 142 (76 per cent left negative to sputum-culture examination over a period of at least three months prior to discharge.

Of 168 men who terminated training between 1948 and 1951, 126 (75 per cent) have remained sputum-negative for three to six years after discharge. This does not include twenty whom we have failed to trace. Only 11 per cent had no active therapy; a similar percentage had chemo-

Final editorial in a series of six on the organization and functions of the Medical Student Committee at the University of Minnesota.

therapy alone. All the others had the addition of some form of collapse therapy.

The work-situation of a similar group of 168 men was most encouraging. Of these 116 (69 per cent) had remained at full work for three to six years following discharge, and 104 (64 per cent) had required no further treatment; six were on part-time work; twenty-seven were not at work, and thirteen we failed to trace.

From this preliminary survey, it is evident that training plus continued treatment can produce results in human happiness and tuberculosis control that repay fully all our efforts, as long as the patient-workers are not worried over their own economic position and that of their families.

The regaining of confidence in ability to work has a marked effect on response to treatment; indeed this confidence is often a factor of greater importance than the administration of drugs and antibiotics.

No further comment is necessary on the value of rehabilitation and vocational training. Here is proof of the conclusions of Sidney H. Dressler and his co-authors in their paper on the needs of the tuberculous in the present trend of treatment.

RICHARD R. TRAIL, M.D.
London, England

MENTAL HEALTH WEEK

Mental Health Week will be observed this year throughout Minnesota and the nation from April 28 through May 4, by proclamation of President Eisenhower.

During this period, mental health will be given the national spotlight, and attention will be focused on the problems, plans and goals of those who work for this important cause.

Mental illness has been termed the No. 1 health problem in this country. Unlike measles and other obvious diseases, mental illness is not easily detected, and millions of Americans can be affected by its devious tentacles, both personally and through closest friends. Even worse, when the symptoms *are* manifested only the smallest percentage of the population know what steps to take to bring about its correction and cure.

Of great importance to business and industry are the three A's of mental illness—accidents, alcoholism and absenteeism. Last year, representatives from Minnesota's industrial and business firms attended a conference in Minneapolis at

which these topics were discussed. This year, a two-day session (April 26 and 27) will be held by members of Minnesota's organized labor and will be known as the Labor Workshop.

Among other aspects of mental health to be publicized during its special week, attention will be called to the "ideal climate" necessary for the containment of mental illness, according to state Mental Health Week chairman Mrs. John B. Ross of Minneapolis.

Such a climate can be created, Mrs. Ross said, by organizing community participation in the Minnesota Association for Mental Health program, by encouraging constructive legislation and by volunteering interest, time and money, during the special week and throughout the year.

For all its terrifying aspects, mental illness can be cured in many cases, said Mrs. Ross. The last few years have shown a tremendous increase in the percentage of cured patients who have been returned to their homes and society.

Quality of treatment plays a large part in these statistics, which range from 45 per cent return at "average" clinics to 70 per cent at those well-equipped and staffed. Building the "average" clinics to "excellent" clinics is a major part of any mental health program.

More than 16,000,000 Americans (1 in 10) are suffering from a mental or emotional disorder. This topic, once taboo, can touch close to home and will receive national attention during Mental Health Week.

Additional information on mental illness is available from the Minnesota Association for Mental Health, 309 E. Franklin Ave., Minneapolis.

EARLY GLAUCOMA DETECTED

A major starting point in glaucoma detection is the use of routine tonometry, results of an 18 months' study by Drs. H. Rommel Hildreth and Bernard Becker of Saint Louis, Mo., have demonstrated.

Routine tonometry (a test to measure tension, as of the eyeball) was performed on all refraction patients over the age of 40 years. Forty-nine out of a total of approximately 2,000 such patients were found to have borderline tensions in the absence of other symptoms or signs of glaucoma or other ocular disease. On the basis of tonography and provocative tests, 69 (72 per cent) of the 97 eyes were classified as glaucoma suspects; and of the 69 eyes so diagnosed, 27 (39 per cent) developed early field loss during a six- to 18-month follow-up period.—HILDRETH, H. R., and BECKER, B.: Routine tonometry, *American Journal of Ophthalmology*, 43:21 (Jan.) 1957.

President's Letter

OUR ANNUAL MEETING

Once again the time is approaching for the physicians of Minnesota, and as many as possible from the neighboring states, to gather in Saint Paul for the annual Scientific Assembly of the Minnesota State Medical Association. When you have had an opportunity to see the program, I am sure that none of you will stay away from Saint Paul willingly on May 13, 14 and 15. The Committee for this Scientific Assembly has arranged an outstanding program. It is a program that any national organization would be proud to present to the physicians of this country and to their communities. Physicians who have national and international reputations have been invited to take part in this program, and all those invited have accepted with alacrity. This in itself indicates the respect with which physicians everywhere view the Minnesota State Medical Association. Symposia, panel discussions, lectures and demonstrations, scientific and commercial exhibits, and a banquet speaker of world-wide renown will occupy three busy days.

On Monday morning, May 13, there will be a panel discussion on "Heart Disease and Pregnancy." Dr. Charles P. Bailey of Philadelphia will discuss "Surgery of the Heart in the Pregnant Patient." Dr. James Metcalfe of Harvard University will discuss "Medical Aspects" of this problem. Dr. Nicholas Aasli of the University of California Medical Center at Los Angeles will speak on "Control of Hypertension in Pregnancy." Dr. I. H. Kaiser of the University of Minnesota will speak on "Obstetrical Problems." The Russell D. Carman Memorial Lecture in radiology will be delivered by Dr. Hans Heinrich Berg of Hamburg, Germany, later that morning.

On Monday afternoon, there will be a symposium on "The Acute Abdomen" with the renowned Dr. H. L. Bockus of Philadelphia as moderator. Dr. N. Logan Leven of Saint Paul; Dr. Leo G. Rigler, Minneapolis; Dr. Harry B. Neel, Albert Lea, and Dr. James C. Cain, Rochester, will participate in this panel.

Any of you who have observed Dr. H. L. Bockus conduct a panel will be expressing regrets for a long time if you do not attend this particular part of the program.

This panel will be followed by a lecture on "Iatrogenic Disorders in Gastroenterology" by Dr. Bockus.

On Tuesday morning there will be a symposium on "Functional Disorders" during which the gastrointestinal aspects will be discussed by Dr. R. S. Ylvisaker, Minneapolis; gynecologic aspects by Dr. Edward A. Banner, Rochester; dermatologic aspects by Dr. Frederick T. Becker, Duluth, and tension states by Dr. Harvey O. Beek, Saint Paul.

After this, your President will discuss some of the problems of the Association and I do hope that you will all be present to help me in solving them.

At 11:00 o'clock Tuesday morning, Dr. Arthur T. Hertig of Boston will present the Arthur H. Sanford Lecture in Pathology, sponsored by the Minnesota Society of Clinical Pathologists.

On Tuesday afternoon a symposium on "The Palliative Treatment of Cancer" will be moderated by the world-renowned Dr. Cornelius P. Rhoads of the Sloan-Kettering Institute for Cancer Research, New York City. Dr. B. J. Kennedy of the University of Minnesota will speak on the use of hormones; Dr. Robert L. Merrick of Saint Paul, on neurosurgery; Dr. Donald S. Childs, Jr., Rochester, on radiation therapy, and Dr. John S. Lundy, Rochester, on the use of drugs in the palliation of the pain of malignant disease.

After this, Dr. Rhoads will deliver a lecture on "The Chemotherapy of Cancer" and physicians of Minnesota will miss a rare treat if they do not attend this lecture.

The speaker at the banquet on Tuesday evening will be Rear Admiral Hyman G. Rickover who is so well-known for his development and construction of the atomic-powered *Nautilus* and who has done outstanding studies of the nation's natural resources. His topic will be "Energy Resources and Our Future."

Dr. Vincent C. Kelley, associate professor of pediatrics at the University of Utah, will give a lecture on "Endocrinopathies in Children" Wednesday morning at 9:00 o'clock. This will be sponsored by the Northwestern Pediatric Society and the Upjohn Company. Following Dr. Kelley's talk, Dr. Cecil Watson of the University of Minnesota will deliver a lecture on "The Practical Appraisal of Liver Function." The latter is the Minnesota Medical Foundation Lecture. It will be followed by a lecture on "The Menopause and Thereafter" by Dr. William H. Masters, associate professor of obstetrics and gynecology at Washington University School of Medicine, St. Louis. Dr. Master's talk is sponsored by the Minnesota Department of Health.

Also for Wednesday morning, the Minnesota Academy of Ophthalmology and Otolaryngology has been most fortunate in obtaining Dr. C. Stewart Nash of Rochester, New York, to present the annual lecture of this organization on "Functional Diseases of the Nose."

On Wednesday afternoon there will be a panel discussion on "Management of Acute Injuries." Dr. Ralph Smith, Minneapolis, will speak on shock; Dr. Harold F. Buchstein, Minneapolis, on head injuries; Dr. Lyle Tongen, Saint Paul, on injuries to the chest, and Dr. E. W. Johnson, Jr., Rochester, on vascular injuries. Truly, no practitioner of medicine could afford not to attend this symposium because of its great value in the everyday practice of the physicians in Minnesota.

I am sure any medical organization would be hard put to find a more practical program of postgraduate education than that which has been planned for you on May 13, 14 and 15.

In addition to this more or less formal program, there will be 23 round-table luncheon discussions on subjects of current interest presented during the noon hour each day by physicians who are authorities in their fields. The space in which these round-table discussions are held is limited. The titles of the subjects to be discussed will be sent to you in the near future, and I would urge you to make your selection as early as possible.

Then, of course, there will be many activities of entertainment including a golf tournament, a skeet shoot, the annual banquet, and the social contacts which all of us make with our colleagues. The Local Arrangements Committee, with Dr. Wallace P. Ritchie, Saint Paul, in charge, has done a fine job of planning these various events.

Finally, of course, there is the Woman's Auxiliary, with Mrs. W. P. Gardner and Mrs. W. P. Ritchie, Saint Paul, in charge of general arrangements. They have planned many interesting activities so that by all means, the ladies should likewise plan to attend the great sessions coming in May.

President, Minnesota State Medical Association

Medical Economics

Edited by the
Committee on Medical Economics,
Minnesota State Medical Association
George Earl, M.D., Chairman

FEDERAL HEALTH LEGISLATION OUTLINED

Civil Aviation Medicine

Public hearings are scheduled to start soon on the Magnuson bill which would elevate medical discipline in civil aviation to a level commensurate with its importance. The aviation subcommittee of the Senate Commerce Committee will conduct the hearings.

Hill-Burton Act

Senator Hubert H. Humphrey (D., Minn.) has filed S.1487 extending Hill-Burton Hospital Construction Act for three more years, until June, 1962. In his explanatory statement, in which he gave population growth as one of the factors of justification, Senator Humphrey also urged Congress to appropriate the maximum authorized amount of \$210 million as the Federal contribution toward hospital expansion this year.

Armed Services Requirements for Medical Personnel Repealed

H.R. 2822 was favorably reported recently by the House Armed Services Committee. This Administration-supported bill repeals the requirement in existing law for professional examinations of medical, dental and veterinary officers of the Army and Air Force as a step toward promotion. Actually the requirement was suspended in World War II and suspended anew in 1951, but the Defense Department wants it stricken from law. The Navy is not involved since its medical and dental personnel are not compelled by statute to undergo professional examination for promotion.

VETERANS AFFAIRS COMMITTEE REVIEWS MEDICAL CARE

Hospitalization and medical care of the nation's veterans was the subject of spirited hearings recently. As in the past, attention was primarily centered on the patient's ability to pay for care of nonservice-connected conditions. Witnesses appearing before the House Veterans' Affairs Com-

mittee represented the AMA, the VFW, AmVets, the DAV, the National Medical Veterans Society and the American Legion.

The AMA argued that good medical care should be available to all who need it, and that to give preference to veterans with nonservice-connected disabilities is an entering wedge to socialized medicine. The AMA supports the Teague Bill to institute tighter economic screening of applicants.

The VFW disputed the figures used by the AMA on the number of patients in VA hospitals for nonservice-connected disabilities. They urged that workmen's compensation fees be turned over to the consultants who care for such cases in VA hospitals. The AmVets reaffirmed their support of the existing policy on care of n-s-c disabilities and pledged aid toward elimination of abuse.

The DAV criticized "the backward steps advocated by the AMA and some others." The same group reminded the committee of their convention endorsement of chiropractic care of veterans on an out-patient basis. The American Legion expressed opposition to any curtailment of benefits and cited survey findings indicating that the majority of n-s-c admission on medical and surgical wards cannot afford to pay.

Dr. Milton V. Davis, Dallas, president-elect of the National Medical Veterans Society, testified in favor of an austere program. NMVS opposes the construction of any more veterans hospitals, and the admission of veterans who have workmen's compensation coverage.

HOSPITAL MEDICAL CARE PAYMENTS TOTAL OVER \$2 BILLION

Hospital and medical care payments to help cover the costs of treatment and physicians' services amounted to \$2.1 billion in 1956, the Health Insurance Institute reports. The figure includes replacement of income lost through sickness or disability. A survey conducted among the country's insurance companies revealed that reimbursements through group insurance plans in force during the year totaled \$1.5 billion or 20.9 per cent over 1955, while payments through individual policies totaled \$601 million, a gain of 12.8 per

cent, for an over-all increase of 18.5 per cent in benefit payments over 1955.

In compiling its report of payment for health care by the insurance companies throughout the United States, the Institute stated that the increase in such payments reflects the continued efforts of the public to pay its doctor and hospital bills through the voluntary non-governmental mechanism.

GOVERNMENT TO SPEND \$14 BILLION FOR WELFARE IN NEXT BUDGET YEAR

In the new budget year, the government will spend \$14 billion in what the Budget Bureau labels "labor and welfare" activities. This does not count spending on some other individual-aid programs—\$5.5 billion for aid to veterans and \$5 billion for aid to farmers, for example. The \$14 billion compares with the \$3.2 billion that the government was spending on the same programs ten years earlier, in 1948. For example, people on old-age insurance benefits (including retired workers and dependents and widows and children of workers) totaled 2.4 million in 1948; the total now is 9.6 million. The number of individuals on public-assistance rolls in 1948 (including needy aged persons, dependent children, the blind, disabled and others) was 4.1 million; today the total is 5.4 million. The total on old-age insurance and public assistance in 1948 was 6.5 million; today the total is 15 million.

Additional welfare programs put additional millions of individuals on the receiving end of the government's activities. School children offer an example. In the new budget year, federal taxes will help pay for 1.7 billion hot lunches for more than 9 million youngsters. There will also be new public housing projects which will provide homes for 35,000 families.

PHYSICIANS THREATEN STRIKE IN BRITAIN

Early in March the British Medical Association endorsed a strike by all of Britain's family doctors against the national health service to press their demands for a 24 per cent wage increase. The group's general council said general practitioners "will be advised to send in their resignations from the service" unless the government meets their pay demands or submits them to arbitration. The doctors were reported to feel they could then further embarrass the govern-

ment by charging fees to any patients requiring medical care and by refusing to issue sickness certificates. Quite a good deal of public sympathy for the doctors' case has been aroused by wide publicity from the press and television.

COSTA RICAN DOCTORS ATTEMPT TO FINANCE RETIREMENT FUND

The medical profession in Costa Rica is trying to finance a retirement fund for its members by a plan to charge drug salesmen 75 cents every time they make a business call on a physician. The 15 major U.S. drug manufacturers who do an estimated \$4 million annual business in Costa Rica have denounced the plan as "an unethical extortion." Most of them say they will close their offices if the retirement fund is not abolished.

Established by the National Medical Union, the plan calls for the salesman or his company to purchase a book of 75-cent coupons. When making his "good will" call to explain new medicine or products to a doctor, the representative must turn over one of the coupons to the doctor or he will not be seen. On the basis of the 120 representatives and salesmen operating in Costa Rica who average a minimum of six calls a day, the medical profession had expected to collect a good \$500 a day for their retirement fund.

Late last month an alternative plan was offered by the medical union. This would finance the fund through a special tax on gross sales of imported drugs. Other Latin American Medical Associations are following developments in Costa Rica very closely.

RUSSIAN TECHNOLOGY IS RAPIDLY APPROACHING U. S. STANDARDS

Recent statistics reveal that Russian technology, only some twenty-five years old, is rapidly approaching U.S. standards. In Russia last year the million who graduated from high schools had successfully passed five years of physics, five years of biology, four years of chemistry, ten years of mathematics through trigonometry, one year of astronomy and six years of foreign languages. In the U. S. in 1950, for example, only four per cent of our high schools were teaching physics; 7 per cent, chemistry; 13 per cent, geometry, and 27 per cent, algebra.

In addition, Russia has thirty-three universities, 180 technical institutes and 3,796 trade schools. The trade schools turn out 70,000 technicians

for assignment to routine scientific tasks. The 266,000 now attending engineering schools are selected, gifted students and are pushed to the limit of their intellectual abilities. Their tuition is free, and they receive pay. Thirty per cent of all students are enrolled in engineering.

In the U.S. there are 218 accredited engineering schools with 156,000 students enrolled. This is only 8 per cent of all college students.

MEDICAL STUDENT STATISTICS COMPILED

A recent AMA report says that medical students who were born and raised in small communities usually go back to small towns to practice after their graduation. Also, the report says, graduates whose prior residence was in the smaller communities are less liable to limit their practice to a specialty. The publicly-supported schools—state or municipal—draw a higher proportion of their students from smaller communities and consequently contribute comparatively more physicians to the smaller communities than do the private schools.

The University of Tennessee Medical School at Memphis turned out more doctors in 1956 than any of the other seventy-six four-year approved medical schools in the United States. The Tennessee school, which operates on a year-round basis and admits several classes annually, graduated 199 young M.D.'s during 1956. It was one of six schools graduating more than 150. The other five and the number of 1956 graduates were: Michigan at Ann Arbor, 189; Jefferson, at Philadelphia, 171; Illinois at Chicago, 159; Texas Medical Branch at Galveston, 151, and Harvard at Boston, 151.

EARNINGS OF PHYSICIANS SURVEYED

Salaried vs. Self-Employed

The typical salaried physician, according to a recent survey, earns only seven-tenths as much as the typical self-employed physician but in the past four years the former has improved his lot somewhat more than has the self-employed man. He also has more free time as he puts in ten hours less per week than the doctor who works for himself; yet both men handle about the same number of patients per working day. Average net earnings of salaried physicians in general practice

is \$10,400 versus \$14,817 for the self-employed; salaried physicians in specialty practice earn about \$12,490 while their self-employed colleagues earn about \$18,000. In industrial practice, however, there is almost no difference between the incomes of salaried and self-employed physicians and in the case of internal medicine, there's a difference of \$600, in favor of the salaried man.

Partnership vs. Group Practice

In contrast to the typical solo physician, the typical doctor in a two-man partnership nets about 33 per cent more from practice. The typical member of a larger partnership or group nets about 43 per cent more than the solo man.

A survey shows that net earnings per doctor of men in a two-man partnership is \$19,966; net per doctor in a larger partnership or group is \$21,460 and for the solo practitioner the total is \$15,028. Men in all three groups seemed to devote about the same amount of time to medicine yet the typical M.D. in combined practice sees five or six more patients per day than does the typical solo doctor.

Male vs. Female Income

Most women physicians earn considerably less than their male colleagues. However, she usually works shorter hours—about 25 per cent shorter—than does the male M.D. Accordingly, she sees only 75 per cent as many patients. Her lighter patient load also leads to a higher ratio of expenses to gross receipts. Even on an hour-for-hour basis, the typical female doctor nets only two-thirds as much from practice as the typical male doctor. The average woman in general practice nets \$8,000 annually versus the male M.D.'s \$14,959; the woman in specialty practice nets \$10,050 in contrast to the male specialist's \$18,027.

MINNESOTA PHYSICIANS CONTRIBUTE \$28,000 TO AMEF

A total of \$28,000 was donated by Minnesota physicians to the American Medical Education Foundation in 1956 for the support of the nation's 83 medical schools; \$19,000 of this total was earmarked by donors to the University of Minnesota Medical School. Dr. Charles Rea, St. Paul surgeon, was Minnesota chairman for the 1956 AMEF campaign.

History of Medicine in Minnesota

THE HISTORY OF MEDICINE IN POLK COUNTY

J. F. NORMAN, M.D.

Crookston, Minnesota

(Continued from January issue)

The First Hospital

The pioneer physicians of Polk County did most of their work in their offices or in homes. This work included whatever surgery was attempted, and, of course, all obstetric cases. The local citizens felt that facilities were lacking for medical care and thus the advantages of a hospital were emphasized and talked about among themselves. Whether any of the doctors in the county took part in this movement toward acquiring a hospital is not known. At a meeting of the County Commissioners on July 25, 1891, it was voted to establish a hospital to be known as the Polk County Hospital in Crookston. While it was to be a county hospital mainly for indigents, provision was made for the admission of paying patients. There is no evidence available that this hospital had facilities for surgery; most of its work consisted in bedside nursing of medical cases.

The Commissioners' records of Polk County (Book B, Page 129)** show the following report: "The Committee appointed on Hospital, having in a report expressed themselves favorable on the erection of a suitable building in the City of Crookston for that purpose. The Board as a whole conjoined in, and adopted the following resolution relative thereto, to wit: Resolved that the amount of three thousand dollars be, and the same is hereby appropriated out of the General Revenue fund of the county for the purpose of purchasing and/or erecting in the City of Crookston, a County Hospital. On motion the County Auditor was instructed to advertise for bids from a physician to attend to the Polk County Hospital, all bids to be filed in the County Auditor's office on or before Jan. 6, 1892. The only bid, that of C. E. Dampier at eleven hundred and fifty-two (\$1,152) dollars per year, including medicine, was rejected. Moved and seconded that when the services of a physician or surgeon are required at the County Hospital, in the City of Crookston, Mathew Watts of said city be called upon to render such services." This was unanimously approved.

M. E. Kirsch, chairman of the Committee on County Hospital submitted the following report which was on motion accepted and ordered published:

"Gentlemen: I hereby submit to you report of the County Hospital for the year ending Dec. 31, 1894:

"Admissions, 42 patients with 12 deaths. Of these deaths there were 4 due to consumption and 2 due to Typhoid; 3 due to heart diseases; 1 liver complaint; 1 Pneumonia and 1 tumor. Number of charity patients admitted during this year: male 34, female 8, total 42. Number of private patients admitted during the year; male 6; female 5, total 11. Total 53. Number of deaths during the year: male 11, female 1. Total 12. Number of visitors during the year 1,663." There were 6 deaths for the year 1895: consumption 1, dropsy 2; typhoid 2 and blood poisoning 1. One of the typhoid deaths was that of Dr. Mathew Watts, a practicing physician of Crookston."

**From the Commissioners' Records of Polk County: Meeting July 25, 1891, Book B, p. 129.

At the December, 1895 meeting, the rules of the County Hospital were amended as follows:

"Moved by Commissioner Norland that the rules governing the county hospital be so amended as to authorize the issuance of tickets of admission to said hospital, the uniform price of such ticket to be \$10.00 each, and that 500 of such tickets be at once printed and placed on sale, the style and conditions of such tickets to be prescribed by the hospital committee."

This is an interesting instance of very early hospital insurance.

Later: "The lease of the County Hospital made by the hospital committee with Dr. W. O. Tessier, together with the bond executed by said Dr. Tessier in connection with said lease were on motion approved."

On request of Dr. Tessier, on September 16, 1897, the above lease was cancelled, and the bondsmen of Dr. Tessier relieved of further liability. On July 26, 1898, the County Auditor was instructed to balance and discontinue the Hospital Fund by charging to the County Revenue Fund the amount overdrawn on the Hospital Fund. Later, the County Auditor was instructed to advertise for bids for the sale of the Polk County Hospital, building and grounds. A bid of Z. Giroux for \$1,500, was accepted September 5, 1902.

Thus ended the life of the first hospital in Polk County, after having had a rough time during its few years of existence.

Following are biographical sketches of the physicians who contributed to Polk County medical history.

Biographical Sketches

Edwin Clark Anderson graduated from the University of Minnesota in 1897 and came to Fertile shortly thereafter. He was a surgeon there for the Northern Pacific Railway Company. He was a member of the Fertile Board of Health and was medical examiner of the Mutual Life of New York, Northwestern Insurance Company of Milwaukee, Mutual Benefit of Newark, New Jersey, Equitable Life of New York; Provident Life and Trust Company of Philadelphia, and the Bankers Life of St. Paul. He was a member of the A.O.U.W. Lodge. Dr. Anderson is listed in Fertile in 1898 with Dr. Arne Nelson and Nels Nelson; in 1900 with Drs. Arne Nelson and John N. Risjford.

William J. Bahnsen, a practicing physician and surgeon who died at the age of thirty-two years at the hands of a murderer, came to Fisher in May, 1887. Born in Germany, he came to the United States as a child. He graduated from the College of Physicians and Surgeons, Chicago, Illinois, in 1885 and was licensed in Minnesota on July 22 of the same year (Certificate No. 1083). He died in August, 1890, after being shot in the back of the head as he was boarding a train after a country call near Fisher. At this time he was located in Crookston. The *Fisher Bulletin* of March 14, 1891 gives the following biographical account:

"Dr. Bahnsen, the victim of Horace Russell, was the third of a family of nine children, six of whom survive him. He was born in Hamburg, Germany, July 31, 1858. When he reached his seventh year, he came to the United States and settled at Rock Island, Illinois. He received a fair education and, having a taste for mercantile life, entered a hardware store, but after two years' trial of that business, abandoned it and secured a clerkship in a jewelry store. He remained in that capacity several years and then entered a medical college in Minneapolis and remained there one term. From there, he went to Chicago and entered the College of Physicians and Surgeons and after receiving his second course of lectures went to New York and completed a course at the Bellevue Hospital. By this time, he had secured a

good knowledge of medicine and concluded to return to Chicago and complete his studies at the P. & S. College. This he accomplished with credit to himself and was awarded a diploma with the congratulations of the professors of the college. He then went to Meeker County, Minnesota, and practiced medicine for one year, but, not being satisfied with his knowledge of medicine and surgery, he went to Europe and studied several years in a hospital at Hamburg and colleges at Berlin and Heidelberg. From both of these famous schools he was awarded diplomas of the highest order of merit. Armed with these formidable certificates and the one awarded him at Chicago, he returned to the United States and on May 16, 1887, arrived in Fisher.

"At this time, his youthful face operated unfavorably against his securing a lucrative practice, and it was only after he had treated complicated diseases that the public became aware of his superior abilities. After he had been a resident of Fisher six months, his fame spread in all directions and was in constant demand as a consulting physician by the profession in Crookston and Grand Forks. His knowledge of surgery was wonderful and many of his successes, had they been performed in St. Paul, Chicago, or any other large city, would have elicited lengthy and favorable plaudits from the press."

The doctor apparently had a smile and good-will for all, never permitting himself to become annoyed by remarks of unfriendly persons. He was a natural-born physician and had he been permitted to enjoy longer life, the people of the vicinity would have had cause to bless his talents and memory, according to *The Bulletin*. He left a widow, the former Annie Elbie, of Fisher, who moved to Decorah, Iowa, after his death.

No death record of Dr. Bahnsen could be found in Polk County or in the State Department of Public Health of North Dakota. (Records in the latter office were checked because of the possibility that he was taken to Grand Forks and that he may have died there. The lack of such a record does not rule out this possibility, as the records of deaths in North Dakota are incomplete prior to 1908). Some pioneers recall that his body was shipped to Rock Island, Illinois, and also that the murderer was freed for some reason. It has not been possible to ascertain the reason for the assassination.

Frank Blakesley was graduated from the Medical department of Hamline University in 1897. He practiced at Fosston and was licensed in Minnesota, June 10, 1897 (Certificate No. 767). We have been unable to find any further history on Dr. Blakesley (also spelled Blakeslee) except that he is listed as practicing in Shevlin (Clearwater County) in 1903 and 1905 and in Bemidji in 1909.

Hamilton Philo Boardman* was in Fishers Landing on Red Lake River for five years in the 1880's. He was born in the late 1850's, the fourth child of Philo Boardman and Jane Hackett Boardman, early settlers in Cascade Township, Olmsted County. Philo Boardman and his wife came to Minnesota in 1855 by ox team and wagon, reaching here after a trip of two months. Philo had been a farmer and stock raiser. After his wife died, he remarried and in 1879 went to Texas where he went into the cattle business. He must have had a good idea of Hamilton's qualities for studying because he willed his land to his older sons with the understanding that they would see to Hamilton's education. The two brothers were Elkanah W. Boardman and Markus J. Boardman, the sister, Margaret (Mrs. William Heaney). Dr. Boardman had his preliminary education in the district village schools. His first medical instruction was received from Dr. W. W. Mayo with whom he studied in the late 70's. His formal medical education was obtained at Bellevue Hospital Medical College, New York, from which he graduated on

*Much of this biography is taken from Dr. Boardman's biography in the "Medical History of Olmsted County," by Norah M. Guthry, MINNESOTA MEDICINE, pp. 375-377 (April) 1950.

March 14, 1880. Three months later—in June—he moved to Oronoco, Olmsted County) where an opening was provided through the drowning of Dr. John N. Farrand. In 1881, however, he moved on to Fishers Landing in Polk County. He stayed there five years. He received his Minnesota license under the "Diploma Law," November 24, 1883 (Certificate No. 401), three days after he had registered in Dakota Territory. Late in 1886, he moved to Oakes, Dickey County, in the Southern part of North Dakota. He practiced in Oakes for fourteen years and established his own hospital in 1901; the hospital seems to have been successful because it needed enlargement in 1902 and again in 1905. In 1907 he retired and moved to California—first to Ocean Park and later to Santa Monica where he died in 1925. Dr. Boardman married Althea McMaster, a schoolteacher, in 1883. She was the daughter of a pioneer settler in Oronoco Township. Althea died in 1903, leaving a fifteen-year-old son, Lees McMaster Boardman. Dr. Boardman married a second time and he was survived by the second wife and his son.

Joseph Bolton, an eclectic physician, was licensed in Minnesota by exemption. In his affidavit filed for the purpose of licensing, he stated that he started to practice in Otter Tail County in 1883 and continued through 1884 and part of 1885. He then practiced in Wilkins County from 1885 to 1887. He supposedly was in East Grand Forks in 1899. Minnesota Directories, however, do not list him between 1890 and 1898, but list his name in East Grand Forks in 1903 and 1905. Polk's Medical Directory does not show his name after 1906. It is not known where he settled after leaving East Grand Forks nor when or where he died.

Otis J. Brown was born in Dayton, Ohio, on April 13, 18.... He graduated from Western Reserve University in 1882 and was licensed in Minnesota, October 6, 1886 (License No. 1275). He came to Red Wing (Goodhue County) in 1885. He was president of the Red Wing Literary Society and was greatly interested in debating. Dr. Brown was county physician and stayed in Red Wing until 1898, when he moved to Crookston, where he practiced until at least 1900. In 1903, he is listed in St. Cloud and from 1905 on in Little Falls. He died on March 28, 1928.

George A. Cable is listed in Crookston in 1886 and in 1890. He graduated in 1873 from the University of Wooster, Medical Department, Cleveland, Ohio. Dr. Cable also practiced in Mentor and Fertile. He was also listed in Villard (Pope County) in 1890. In 1895 and 1898, he was in Minneapolis; in 1903 and 1905, in San Francisco, California. He received his license December 31, 1883 (License No. 692). He died October 10, 1908.

Magnus A. F. Carmentan (Cormotan) is listed in the "Official Register, Physicians in Minnesota, 1883-1890"; he was licensed as a "regular" physician (License No. 450-3) on December 19, 1883, at Fosston. He was licensed by exemption, and no school of graduation is known. Minnesota Directories list him at Pelican Rapids (Otter Tail County) in 1890 and at Fosston in 1895 as deceased.

Jackson S. Chapin was born in Highman, Wisconsin, January 13, 1856. He attended Bennet Medical College, Chicago, Illinois, and practiced in Ohio as assistant to a county doctor. He started practice in Euclid in 1882. He was not registered, but was allowed to continue his work at Euclid by virtue of his years of practice, qualifications and his long apprenticeship in Ohio. He was a kindly gentleman and very attentive to his patients. He was a widespread reputation for his care and success in treating typhoid. He died suddenly in 1925 at the home

of a patient for whom he was caring. His wife still survives him and is over 90 years old (1953). He is no doubt identical with Dr. G. S. Chapin listed in the "Official Register, Physicians in Minnesota, 1883-1890," with license No. 849-1.

Walter Clark is listed in Mentor in 1886, 1890 and 1893. This seems to be the only information available on Dr. Clark. He was not licensed in Minnesota.

Charles E. Dampier, a pioneer physician and surgeon in the northwest, was an eminent citizen of Crookston. He was a native of Canada, born in Waterloo, Province of Quebec, June 5, 1854. Two years later, his parents, Edward and Charlotte (Parmalee) Dampier, came to Minnesota. (Edward Dampier was born in Paris, but was of English parentage, and his wife was a native of Vermont.) They located in Stell County, in what is now Lamand township, in 1856, and were the second family of white settlers in that section. A few years later Edward Dampier moved to Meridian township, where he lived until 1862. In that year, he went to Dakota County and there rented a farm. He also resided for a time in Fergus Falls and Northfield. He was engaged in the hotel business in Northfield when the town was raided by the Younger Brothers, and it was from a window of his hotel that Dr. Wheeler shot Clell Miller, a member of the gang. Dr. Wheeler gained possession of the body of Clell Miller and when he returned to Medical School at the University of Michigan, he still had possession of this cadaver. The story, perhaps apochryphal, was that both Charles Dampier and Wheeler were asked whether each had material for anatomy. Dampier answered, "Yes, sir." The question passed on to Wheeler, who also answered, "Yes, sir." He was then asked, "Where did you get it?" Wheeler replied, "I had to go out and shoot one." After graduation, Dr. Dampier kept the gun and Dr. Wheeler had the skeleton of Clell Miller in a back closet at his office in Grand Forks, North Dakota, where it remained until recently when the place burned down. Edward Dampier served as first Lieutenant of his company which was detailed to detached duty in Minnesota during the Civil War. On receiving his honorable discharge in 1865, he returned to Dakota County and purchased a farm near Castle Rock. As an early settler of the state, he endured the hardships and trials of that time, a worthy citizen of the new commonwealth.

Charles Dampier, one of seven children, was reared in Minnesota and received his early education in the country schools. He completed his preparatory studies in an academy at Elgin, Illinois, and attended Carleton College. He began his professional studies in Northfield under Dr. C. L. Armington and, in 1876, entered the medical college of the University of Michigan, receiving his degree in 1878. He located at Dell Rapids, South Dakota, and practiced there for about six months, then returned to Minnesota and to Northfield. He was licensed to practice in Minnesota in 1883. In the following year, he went to Crookston where he enjoyed a successful practice. Dr. Dampier has never regarded his medical education as finished but continued his scientific studies and research, keeping in touch with the many developments and achievements of the medical world. He took several postgraduate courses, two of them in Chicago. He served for five years as councilor of the First District for the State Medical Association and was a member of the American Medical Association, and the Red River Valley Society. He received a number of important federal appointments. He was county examiner for the sanatorium at Walker, Minnesota, secretary of the Board of Pension Examiners, and for twenty-five years had been the city health officer. He held the position of local surgeon for the Northern Pacific Railroad twenty-five years. Aside from his professional duties, Dr. Dampier was identi-

fied with public interests as secretary and treasurer of the school board and as treasurer of the Building and Loan Association. He was a member of the Masonic fraternity, a Shriner and Past Eminent Commander of the Crookston Commandery and had been treasurer of the local chapters for more than thirty years. He was a charter member of the Elks' Lodge and had served as treasurer of that order for a number of years. He died February 20, 1923, at Bethesda Hospital, Crookston, at the age of sixty-eight.

Charles H. Denniston was graduated in 1875 from Bellvue Hospital Medical College, New York City. He was in Crookston as early as 1886 and was listed there in 1890 through at least 1909. He limited his work to medical work. He was a retiring gentleman, and never became well known. He was licensed December 28, 1883 (License No. 508). It is not known where or when he died.

Alexander H. Dunlop, one of the leading physicians and surgeons of Crookston, was eminently connected with the medical profession of the county from 1882, when he first engaged in practice in Crookston. He was born in Ontario, Canada, September 14, 1857. His father, John Dunlop, was a native of Ontario and his wife, Julia (Ellis) Dunlop, was born in Edinburgh, Scotland. John Dunlop was a lumber man and mill owner and lived in Canada throughout his life. Of their family of four sons and three daughters, Dr. Alexander Dunlop was the only one who did not reside in Canada. He was reared in that country and received his early education in the public schools and then became a student at Queens College at Kingston. After graduating from that institution in 1875, he began to prepare himself for the medical profession. He studied for a few months under Dr. Lafferty of Kingston, and in the winter of the same year he entered McGill College. In 1882, he received his degree and came to Crookston where he continued to pursue his professional duties. He became a citizen of the United States in the same year and was licensed in 1883. No small part of his success was due to years of keen study and a constant alertness to the rapid advances made in medical discoveries. Dr. Dunlop took postgraduate work each year, either in New York clinics or at McGill College. He was a member of the Minnesota Medical Association, the Red River Valley Medical Society and the American Medical Association.

Aside from his private practice, Dr. Dunlop held the position of local surgeon for the Great Northern Railroad for several years. He was married in 1912 to Annie Bolie, a native of Minnesota. Dr. Dunlop was a member of the Masonic order, the Modern Woodmen, and the Elk Lodge. He impressed one as being a keen mental type and was a good diagnostician. He did considerable surgery and was on the staffs of Bethesda and St. Vincent Hospitals. He had a large personal following, was "good company" and was endowed with a marked sense of humor. He died March 19, 1945, at the age of eighty-seven, a few years after he had retired, and was buried in Crookston. Dr. Dunlop left no children. His wife still lives in Crookston (1953).

Francis X. Farley settled in Crookston in 1886 and practiced medicine there until approximately 1910. He graduated in 1881 from the Michigan College of Medicine and was licensed in Minnesota in November, 1883. He left Crookston to retire about 1910. It is said that he moved to Los Angeles, California, in 1913, but he apparently did not practice there.

6:30 P.M.—Dinner.....Minnesota Chapter,
American College of Chest Physicians, Lowry Hotel

MONDAY, MAY 13

Luncheons

12:00 noon—American Medical Women's Association,
Minnesota Branch..Saint Paul Athletic Club

Dinners

6:00 P.M.—Minnesota Academy of General Practice.
Mezzanine Ballroom, Lowry Hotel.

6:00 P.M.—Minnesota Radiological Society.
Minnesota Club.

Open House

9:00 P.M.—Minnesota State Medical Association.
Continental Room, Saint Paul Hotel.

TUESDAY, MAY 14

Luncheons

12:15 P.M.—Minnesota Society of Clinical Pathologists.

Dinners

6:00 P.M.—Minnesota Society of Clinical Pathologists.
University Club.

7:00 P.M.—Minnesota State Medical Association,
Annual Banquet, Continental Room, Saint
Paul Hotel.

WEDNESDAY, MAY 15

Dinners

6:30 P.M.—University of Minnesota Class of 1939
Reunion. Minnesota Club.

ROUND TABLES

Saint Paul Hotel—12:15 P.M.

MONDAY, MAY 13

Broncho-esophageal Problems Including Foreign Bodies
COLEMAN J. CONNELLY, Saint Paul

Upper Gastro-Intestinal Hemorrhage

STANLEY R. MAXEINER, JR., Minneapolis

Urinary Tract Infections.....HAROLD J. WALDER, Duluth

Anticoagulants: Indications and Contraindications

SIDNEY O. HUGHES, Winona

Induction of Labor.....ALBERT F. HAYES, Saint Paul

Problems in Back Injuries.....D. L. MCCAIN, Saint Paul

Heart Disease Subject

CHARLES P. BAILEY, Philadelphia, Pa.

Medical Problems in Pregnancy

JAMES METCALFE, Boston City Lying-in
Hospital, Boston, Mass.

TUESDAY, MAY 14

Diagnosis of Chest Diseases

THOMAS J. KINSELLA, Minneapolis

Adrenal Steroids.....R. G. SPRAGUE, Rochester

The Dangerous Placenta

KERMIT E. KRANTZ, Assistant Professor of
Obstetrics and Gynecology, School of
Medicine, University of Arkansas, Little
Rock, Arkansas

Infertility, a Family Unit Problem

WILLIAM H. MASTERS, Associate Professor
of Obstetrics and Gynecology, Washington
University School of Medicine, St. Louis,
Missouri

Biliary Tract Disease.....W. J. FINKELNBURG, Winona

PRELIMINARY PROGRAM

Chronic Ulcerative Colitis and Regional Enteritis
B. M. BLACK, Rochester

Carcinoma *in situ* of the Uterine Cervix
ARTHUR T. HERTIG, Head, Department of Pathology, Harvard University Medical School, Boston, Mass.

Cancer Subject
C. P. RHOADS, Sloan-Kettering Institute for Cancer Research, New York, New York

WEDNESDAY, MAY 15

Diagnosis of Lesions of the Anus and Rectum
WILLIAM C. BERNSTEIN, Saint Paul

Practical Points in the Use of Digitalis
S. H. BOYER, JR., Duluth

Diarrhea.....PHILIP W. BROWN, Rochester

Role of Radio-iodine in Thyroid Disease
ELMER C. PAULSON, Saint Paul

The Discriminate Use of Chemotherapy
WESLEY W. SPINK, University of Minnesota

Acute Renal Failure.....HOWARD M. ODELL, Rochester

The Eyegrounds in Everyday Practice
VIRGIL J. SCHWARTZ, Minneapolis

GENERAL SESSION

Saint Paul Municipal Auditorium

MONDAY, MAY 13

Morning Session

Chairman: J. P. MEDELMAN

A.M.

8:30 Visit Scientific and Technical Exhibits

9:00 MINNESOTA HEART ASSOCIATION PANEL

Heart Disease in Pregnancy

RODNEY F. STURLEY, Saint Paul, Chairman
JOHN F. BRIGGS, Saint Paul, Moderator

Surgical Treatment of Pregnant Heart Cases

CHARLES P. BAILEY, Professor and Head, Department of Thoracic Surgery, Hahnemann Medical College, Philadelphia, Pa.

General Problems of the Heart in Pregnancy

JAMES METCALFE, Associate Physician, Boston City Lying-in Hospital, Boston, Mass.

Hypertension and Toxemia in Pregnancy

NICHOLAS S. AASLI, Associate Professor of Obstetrics and Gynecology, University of California Medical Center, Los Angeles, Calif.

Obstetrical Problems in Pregnant Heart Cases

IRWIN H. KAISER, University of Minnesota

Question and Answer period.

Intermission

11:00 RUSSELL D. CARMAN MEMORIAL LECTURE

Hiatus Hernia: Facts and Problems

PROF. DR. HANS HEINRICH BERG, Hamburg, Germany

Afternoon Session

Chairman: W. P. FINKELNBURG

P.M.

12:15 Miscellaneous Luncheons

12:15 Round Table Luncheons

1:30 Visit Scientific and Technical Exhibits

2:00 *The Acute Abdomen*—Panel Discussion
HENRY L. BOCKUS, Philadelphia, Pa., Moderator

Surgical Considerations in the Upper Abdomen
N. LOGAN LEVEN, Saint Paul

Surgical Considerations in the Lower Abdomen
HARRY B. NEEL, Albert Lea

Roentgenologic Aspects and Indications for Roentgenography

LEO G. RIGLER, University of Minnesota

Diagnostic Problems of the Acute Abdomen
J. C. CAIN, Rochester

Question and Answer period.

3:15 INTERMISSION

Visit Scientific and Technical Exhibits

4:00 *Iatrogenic Disorders in Gastroenterology*

HENRY L. BOCKUS, Professor and Chairman, Department of Medicine, University of Pennsylvania Graduate School of Medicine, Philadelphia, Pennsylvania

5:15 *Obstetric Manikin Demonstration*

KERMIT E. KRANTZ, Assistant Professor of Obstetrics and Gynecology, School of Medicine, University of Arkansas, Little Rock, Arkansas

5:15 Visit Scientific and Technical Exhibits

6:00 Special Dinners

9:00 Open House—Saint Paul Hotel

GENERAL SESSION

Saint Paul Municipal Auditorium

TUESDAY, MAY 14

Morning Session

Chairman: W. S. NEFF

A.M.

8:30 Visit Scientific and Technical Exhibits

9:00 *Functional Disorders*—A Symposium

Gastrointestinal Aspects

R. S. YLVISAKER, Minneapolis

Gynecology

E. A. BANNER, Rochester

Dermatology

F. T. BECKER, Duluth

Tension States

HARVEY O. BEEK, Saint Paul

Question and Answer period.

10:00 *Presidential Address*

J. A. BARGEN, Rochester

PRELIMINARY PROGRAM

Intermission

Visit Scientific and Technical Exhibits

11:00 ARTHUR H. SANFORD LECTURE

Essentials of Endometrial Pathology

ARTHUR T. HERTIG, Shattuck Professor of Pathological Anatomy and Head, Department of Pathology, Harvard University Medical School, Boston, Mass.

Afternoon Session

Chairman: B. M. BLACK

P.M.

12:15 Special Luncheons

12:15 Round Table Luncheons

1:30 Visit Scientific and Technical Exhibits

2:00 *Palliative Treatment of Cancer*—A Panel
C. P. RHOADS, New York City, Moderator

Use of Hormones—B. J. KENNEDY, University of Minnesota

By Neurosurgery
R. L. MERRICK, Saint Paul

Radiation Therapy
DONALD S. CHILDS, JR., Rochester

By Drugs
JOHN S. LUNDY, Rochester

Question and Answer period.

Intermission

Visit Scientific and Technical Exhibits

4:00 MINNESOTA DIVISION, AMERICAN CANCER SOCIETY LECTURE

Chemotherapy of Cancer

C. P. RHOADS, Director, Sloan-Kettering Institute for Cancer Research, New York, New York

5:15 *Obstetric Manikin Demonstration*
RUSSELL N. FRY, Minneapolis

5:15 Visit Scientific and Technical Exhibits

Tuesday Evening

7:00 Annual Banquet—Continental Room, Saint Paul Hotel
Presiding—J. A. BARGEN, Rochester

Introduction of Woman's Auxiliary President:
MRS. C. L. OPPEGAARD, Crookston

Presentation: Fifty-Club Certificates; Southern Minnesota Medical Association Medal; Distinguished Service Medal

Speaker: REAR ADMIRAL HYMAN G. RICKOVER, Washington, D. C.—“Energy Resources and Our Future”

GENERAL SESSION

Saint Paul Municipal Auditorium

WEDNESDAY, MAY 15

Morning Session

Chairman: R. P. BUCKLEY

A.M.

8:30 Visit Scientific and Technical Exhibits

9:00 NORTHWESTERN PEDIATRIC SOCIETY LECTURE

Endocrinopathies in Children

VINCENT C. KELLEY, Associate Professor of Pediatrics, University of Utah College of Medicine, Salt Lake City, Utah

9:40 MINNESOTA MEDICAL FOUNDATION LECTURE

The Practical Appraisal of Liver Function
CECIL WATSON, Professor and Head, Department of Medicine, University of Minnesota

Intermission

Visit Scientific and Technical Exhibits

11:00 *The Menopause and Therafter*
WILLIAM H. MASTERS, Associate Professor of Obstetrics and Gynecology, Washington University School of Medicine, St. Louis, Missouri

11:30 *Functional Disorders of the Nose*
C. STEWART NASH, Consultant to the Faculty, University of Rochester School of Medicine and Dentistry, Rochester, New York

Afternoon Session

Chairman: D. S. AMATUZIO

P.M.

12:15 Round Table Luncheons

1:30 Visit Scientific and Technical Exhibits

2:00 *Managment of Acute Injuries*—A Panel
CLAUDE HITCHCOCK, Minneapolis, Moderator

Shock
RALPH SMITH, Veterans Hospital, Minneapolis

Head Injuries
HAROLD BUCHSTEIN, Minneapolis

Chest Injuries
LYLE TONGEN, Saint Paul

Vascular Injuries
E. W. JOHNSON, JR., Rochester

Question and Answer period.

Woman's Auxiliary

35th Annual Meeting

PROGRAM

MONDAY, MAY 13, 1957

A.M.

- 9:00—*Registration*Mezzanine, Hotel Lowry
 9:30—*Transportation for Tour*
 Leave from Fourth Street entrance—Hotel Lowry

- 10:00—*Tour*Minnesota Mining Research Center
 10:45—*Executive Board Meeting*....Women's City Club

P.M.

- 1:00—*Executive Board Luncheon*....Women's City Club (\$2.25)
 2:45—*Transportation to Tea*
 Leave from Fourth Street entrance—Hotel Lowry
 3:00-4:30—*Tea*
 Home of Dr. and Mrs. Philemon Roy, 1 Raccoon Road, North Oaks, Minn.
 All visiting women are invited
 9:00—*Open House*....Continental Room, St. Paul Hotel
 Open to all visiting women and their husbands

TUESDAY, MAY 14, 1957

A.M.

- 9:00—*Registration*Mezzanine, Hotel Lowry
 9:30—*Annual Meeting*.....Fiesta Room, Hotel Lowry
 Open to all members of the Auxiliary
 Presiding—MRS. L. P. HOWELL, Rochester, President
 Pledge of Allegiance and Auxiliary Pledge—MRS. EZRA BRIDGE, Cannon Falls
 "I pledge my loyalty and devotion to the Woman's Auxiliary to the American Medical Association. I will support its activities, protect its reputation and ever sustain its high ideals."
 Address of Welcome—MRS. CHARLES FROATS, President, Ramsey County Medical Auxiliary
 Response—MRS. CHESTER THIEM, Mankato
 Presentation of Convention Chairmen—MRS. W. P. GARDNER and MRS. W. P. RITCHIE
 In Memoriam Service—MRS. CHARLES WASS, Saint Paul
 Reports
 Election of Officers

P.M.

- 1:00—*Annual Luncheon*
 Mezzanine Ballroom, Hotel Lowry
 Tickets \$2.25
 Installation of Officers—MRS. H. H. FESLER, Saint Paul
 Installation of President and Presentation of President's Pin—MRS. J. F. NORMAN, Saint Paul

- 7:00—*Annual Banquet*

Continental Room, St. Paul Hotel

- Presiding—J. A. BARGEN, Rochester
 Introduction of MRS. C. L. OPPEGAARD, Woman's Auxiliary President
 Presentation of Fifty Club Certificates
 Presentation of Southern Minnesota Medical Association Medal
 Presentation of Distinguished Service Medal
 Speaker—REAR ADMIRAL HYMAN G. RICKOVER, U. S. Navy, "Energy Resources and Our Future"

WEDNESDAY, MAY 15, 1957

A.M.

- 9:30—*Breakfast*Ramsey Room, Hotel Lowry
 (All visiting women guests of Ramsey County Medical Auxiliary)
Please Be Sure to Visit the Scientific and Technical Exhibits at the Saint Paul Municipal Auditorium

Committees

All members of the Ramsey County Medical Auxiliary
General Arrangements—Mrs. Walter P. Gardner and Mrs. Wallace P. Ritchie.

Registration—Mrs. J. P. Medelman, Chairman; Mrs. Don Derauf, Mrs. Leroy Fox, Mrs. John Madden, Mrs. Leo Nash, Mrs. O. I. Sohlberg.

Reservations—Mrs. John Meade.

Tickets—Mrs. L. T. Simons, Chairman; Mrs. Frank Babb, Mrs. Charles Eginton, Mrs. W. A. Gleason, Mrs. Donald Lannin.

Hospitality—Mrs. H. J. Wolff and Mrs. W. H. Von der Weyer.

Board Luncheon—Mrs. R. K. Grau, Chairman; Mrs. Alexander McEwan, Mrs. E. R. Sterner.

Tea—Mrs. Philemon Roy, Chairman; Mrs. Frank Adair, Mrs. Charles Fogarty, Jr., Mrs. M. Dudley Hilker, Mrs. Douglass Kusske, Mrs. B. G. Lannin, Mrs. James Ralph.

Annual Meeting—Arrangements, Mrs. Wallace Ritchie.

Annual Luncheon—Mrs. Walter Carley and Mrs. Eugene Scott.

Pages—Mrs. S. M. Loken, Chairman; Mrs. O. E. Enroth, Mrs. Benjamin F. Fuller, Mrs. John A. McNeill, Mrs. Albert G. Miller.

Breakfast—Mrs. H. O. Peterson, Chairman; Mrs. Frederick P. Army, Mrs. F. J. Bonello, Mrs. Louis A. Nelson, Jr.

Flowers—Mrs. Herbert Johnson and Mrs. Ralph L. Olsen.

Press—Mrs. Gerhard Knutson and Mrs. A. B. Rosenfield.

Music—Mrs. Robert W. Holman.

Tour and Transportation—Mrs. L. G. Culver, Chairman; Mrs. Carleton W. Leverenz, Mrs. Burtis J. Mears, Mrs. B. B. Souster.

Meetings and Announcements

TATE

MINNESOTA STATE MEDICAL ASSOCIATION, 64th annual meeting, Saint Paul, May 13, 14 and 15, 1957.

NATIONAL

American Congress of Physical Medicine and Rehabilitation, thirty-fifth annual scientific and clinical session, Los Angeles, September 8-13, 1957.

American Goiter Association, Hotel Statler, New York, New York, May 28-30, 1957. John C. McClintock, M.D., Secretary, 149½ Washington Avenue, Albany 10, New York.

The Children's Hospital of Philadelphia. Three short refresher courses. "Pediatric Advances for Pediatricians and General Practitioners," May 27-31, 1957. "Practical Pediatric Hematology," June 3-5, 1957. "Blood Group Incompatibilities and Erythroblastosis Fetalis," June 6-7, 1957. Irving J. Wolman, M.D., Children's Hospital of Philadelphia, 1740 Bainbridge Street, Philadelphia 46, Pennsylvania.

First American Post-Graduate Assembly in Fertility and Sterility, New York Medical College-Metropolitan Medical Center, May 18-31. Dr. Ralph E. Snyder, Dean, New York Medical College, 1249 Fifth Avenue, New York 29, New York.

New York University Post-Graduate Medical School. Management of Chronic Kidney Diseases, June 24-25, Dr. Lawrence G. Wesson. Office of Associate Dean, New York University Post-Graduate Medical School, 550 First Avenue, New York 16, New York.

New York University Post-Graduate Medical School. Management of Hypertension, June 26-27, Dr. J. Marion Bryant. Office of Associate Dean, New York University Post-Graduate Medical School, 550 First Avenue, New York 16, New York.

Postgraduate Course on Gastroenterology, University of Colorado School of Medicine, Denver, Colorado, May 13-15, 1957. Co-sponsored by the American Gastroenterological Association. Office of Postgraduate Medical Education, University of Colorado Medical Center, 4200 East Ninth Avenue, Denver 20, Colorado.

University of Pittsburgh School of Medicine, Department of Surgery, Section of Anesthesiology—Postgraduate Symposium on the Basic Sciences Related to Anesthesiology, June 10-14, 1957. Write to Chairman of the Committee on Graduate Medical Education, Uni-

versity of Pittsburgh School of Medicine, 3941 O'Hara Street, Pittsburgh 13, Pennsylvania.

INTERNATIONAL

Canadian Medical Association, Edmonton, Alberta, Canada, June 17-21. Dr. A. D. Kelly, 150 St. George Street, Toronto 5, Ontario, Canada.

Congress of International Association for Study of the Bronchi, Lisbon, Portugal, May 25-26, Prof. F. Lopo de Varvalho, 138 rua de Junqueira, Lisbon, Portugal.

Congress of International Society for Cell Biology, St. Andrews, Fife, Scotland, August 28-September 3. Prof. H. G. Callan, Bell Pettigrew Museum, The University, St. Andrews, Fife, Scotland.

Congress of International Society of Orthopedic Surgery and Traumatology, Barcelona, Spain, September 16-21. International Society of Orthopedic Surgery and Traumatology, 34 rue Montoyer, Brussels, Belgium.

Congress of International Society of Surgery, Mexico City, Mexico, October 27-November 2. Dr. L. Dejardin, 141 rue Belliard, Brussels, Belgium.

Fourth International Poliomyelitis Conference, Geneva, Switzerland, July 8-12. Registration deadline, April 1. Fourth International Poliomyelitis Conference, Secretariat, Hotel du Rhone, Geneva, Switzerland.

Inter-American Congress of Pan American Medical Association, Mexico City, Mexico, November 18-22. Dr. Joseph J. Eller, 745 Fifth Avenue, New York 22, New York.

International Conference on Audiology, St. Louis, Missouri, May 13-16. Dr. S. Richard Silverman, 818 South Kingshighway, St. Louis, Missouri.

International Congress of Clinical Pathology, Brussels, Belgium, July 15-20. Prof. M. Welsch, Université de Liege, 32 Blvd. de la Constitution, Liege, Belgium.

International Congress of Dermatology, Stockholm, Sweden, July 31-August 6. Dr. C. H. Floden, Karolinska, Sjukhuset, Hudkliniken, Stockholm 60, Sweden.

International Congress of Electroencephalography and Clinical Neurophysiology, Brussels, Belgium, July 21-28. Dr. R. G. Bickford, Mayo Clinic, Rochester, Minnesota.

International Congress of International Society of Bronchoesophagology, Philadelphia, Pennsylvania, May 12-13. Dr. Chevalier L. Jackson, 3401 North Broad Street, Philadelphia.

International Congress on Medicine and Surgery, Turin, Italy, June 1-9. Secretariat, Minerva Medica, Corso Bramante 83-85, Turin, Italy.

International Congress of Neurological Sciences, Brus-

sels, Belgium, July 21-28. Dr. Pearce Bailey, National Institutes of Health, Bethesda 14, Maryland.

International Congress of Neurosurgery, Brussels, Belgium, July 21-28. Dr. William B. Scoville, 85 Jefferson Street, Hartford, Connecticut.

International Congress of Neuropathology, Brussels, Belgium, July 21-28. Dr. Ludo J. Bogaert, 47 rue de l'Harmonie, Antwerp, Belgium.

International Congress of Nutrition, Paris, France, July 24-29. Congress International de Nutrition, 71 Blvd. Pereire, Paris 17e, France.

International Congress of Otolaryngology, Washington, D. C., May 5-10. Dr. Paul H. Molinger, 700 North Michigan Avenue, Chicago 11, Illinois.

International Congress on Rheumatic Diseases, Toronto, Ontario, Canada, June 23-28. International Congress on Rheumatic Diseases, P.O. Box 237, Terminal "A," Toronto, Ontario.

International Gerontological Congress, Merano-Bolzano, Italy, July 14-19. Segreteria, Quarto Congresso Internazionale de Gerontologia, Viale Morgagni, 85, Firenze, Italy.

International League Against Epilepsy, Brussels, Belgium, July 21-28. Dr. Radermecker, Institut Bunge, 59 rue Philippe Milliot, Berchem, Antwerp, Belgium.

International Symposium on Medical-Social Aspects of Senile Nervous Diseases, Venice, Italy, July 20-21. Secretariate, Viale Morgagni 85, Firenze, Italy.

International Voice Conference (Laryngeal Research Function and Therapy), Chicago, Illinois, May 20-22. Dr. Hans von Leden, 30 North Michigan Avenue, Chicago 2, Illinois.

Neuroradiologic Symposium, Brussels, Belgium, July 21-28. Professor Melot, Hôpital Universitaire St. Pierre, Brussels, Belgium.

Pan-Pacific Surgical Association, seventh congress, Honolulu, Hawaii, November 14-22, 1957. Write Dr. F. J. Pinkerton, director-general of the Pan-Pacific Surgical Association, Room 230, Young Building, Honolulu, Hawaii.

Third International Medical-Surgical Meeting, Torino, Italy, June 1-9, 1957. Includes four international congresses (International Congress on Nuclear Medicine, International Congress on Photobiology, and International Congress on the Problems of the Goitre), seven national congresses (on chemotherapy, gastroenterology, surgery), ten symposia (European Society of Cardiovascular Surgery, Symposium on Artificial Heart-Lung Machines), and many meetings on the various medical and surgical specialties. Write: Secretary-General, Minerva Medica, Corso Bramante 83-85, Torino, Italy.

William Harvey Tercentenary Congress, Royal College of Surgeons, London, England, June 3-7, 1957. Dr. D. Geraint James, Harveian Society of London, 11 Chandos Street, Cavendish Square, London W. 1, England.

NEW YORK UNIVERSITY POST-GRADUATE MEDICAL SCHOOL ANNOUNCES COURSES

Spring and early summer postgraduate courses to be held at the New York University Post-Graduate Medical School are as follows:

Anesthesiology—full time—May 6-31.

Cardiology—full time—May 6-24.

Orthopedics in General Practice—full time—June 10-12.

Symposium on Modern Therapeutics in Internal Medicine—full time—June 10-21.

Management of Chronic Kidney Disease—full time—June 24-25.

Management of Hypertension—full time—June 26-27.

Further information may be obtained from the Office of the Associate Dean, Post-Graduate Medical School, 550 First Avenue, New York 16, New York.

SYMPOSIUM ON ALCOHOLISM

"The Treatment of the Alcoholic" will be the theme of a symposium on alcoholism for physicians to be held at the Center for Continuation Study, University of Minnesota, May 23-24, 1957, under the joint sponsorship of the University and the Minnesota Department of Health.

Dr. Lorant Forizs, medical director of the Florida Alcoholic Rehabilitation Program, will speak on motivating the alcoholic patient and group treatment of alcoholics. Dr. R. Gordon Bell, director of the Bell Clinic, Willowdale, Ontario, will talk on the nature of alcoholism and the use of drugs in follow-up treatment. Dr. Bell is one of the developers of Temposil, a new drug to help alcoholics remain away from alcohol. Dr. Vernelle Fox, medical director of the Georgian Clinic, Atlanta, Georgia, will speak on the use of the ataractic drugs in the therapy of alcoholism.

Registration is limited and a \$5.00 fee will be charged. The conference is open to all physicians. Applications may be secured from the Center for Continuation Study, University of Minnesota, Minneapolis 14, Minnesota.

FOURTEEN FELLOWSHIPS IN PSYCHIATRY ANNOUNCED

The American Psychiatric Association has announced the award of fourteen fellowships in psychiatry, sponsored by the Smith, Kline & French Foundation, an independent philanthropic arm of Smith, Kline & French Laboratories, pharmaceutical manufacturers. The fellowships, which are administered by a committee named by the American Psychiatric Association, were established because it was believed that it is essential to bring new knowledge of therapies, techniques and practices to bear on the treatment and care of patients in public mental hospitals and schools for the retarded, and that there is a dire need for recruitment of a vast new corps of psychiatrists.

Seven main types of fellowships are available: support for advanced training for full-time staff psychiatrists of public mental hospitals and schools for the retarded;

COMPREHENSIVE VAGINITIS REGIMEN

Powder Insufflation

Tablet Insertion

Floraquin® Rebuilds the Defense Mechanism in Vaginitis

Combined office and home treatment with Floraquin provides a comprehensive regimen which encourages restoration of the normal "acid barrier" to pathogenic infection.

Vaginal secretions normally show a high degree of protective acidity (pH 3.8 to 4.4). When this "acid barrier" is disturbed, growth of benign Döderlein bacilli is inhibited and that of pathogens encouraged. Floraquin not only provides an effective protozoacide and fungicide (Diodoquin®) destructive to pathogenic trichomonads and yeast, but also furnishes sugar and boric acid for reestablishment of the normal vaginal acidity and regrowth of the normal protective flora.

Suggested Office Floraquin Insufflation

"... the vagina is treated daily by swabbing with green soap and water, drying and insufflation of Floraquin powder."*

Suggested Home Floraquin Treatment

"The patient is also issued a prescription for Floraquin vaginal suppositories which she is instructed to insert high into the vagina each evening. On the morning following each application of these suppositories, the patient should take a vinegar water douche. . . ."

A Floraquin applicator is supplied with each box of 50 Floraquin tablets. G.D. Searle & Co., Chicago 80, Illinois, Research in the Service of Medicine.

*Williamson, P.: Trichomonad Infestation, M. Times 84:929 (Sept.) 1956.

SEARLE

*Cleans like
magic . . . no more
scrubbing with*

KLER-RO®

ULMER

For surgical instruments, laboratory glassware, rubber goods and linens.

Soaks clean . . . removes dried blood, pyrogens, plasma, serums and mucus . . . eliminates necessity of hand scrubbing.

Will not etch glassware, leaves it sparkling clean. Will not pit stainless steel. Has a nearly neutral pH. Kler-ro does not cake but dissolves quickly and is safe and economical to use.

FOURTEEN FELLOWSHIPS IN PSYCHIATRY ANNOUNCED

(Continued from Page 288)

awards to hospitals for visiting lectureships and for teaching fellowships; support for medical schools, teaching centers, et cetera, for extension training programs; student fellowships to encourage talented medical students to engage in summer activities in psychiatry, with the aim of drawing them into psychiatry as a life work; medical fellowships to encourage broadened skill in psychiatric problems of everyday practice by physicians other than psychiatrists; foreign scholar lectureships to bring outstanding men to the United States; and residency training fellowships under unusual circumstances.

One of the grants made is to the University of Minnesota Medical School to permit two medical students to receive support for an eight-week period between their junior and senior years while being attached to the Child Psychiatry Service of University Hospitals. Another grant is to the Mayo Clinic to permit three students at the University of Minnesota Medical School to participate in the psychiatric program at the Mayo Clinic for ten weeks in the summer of 1957 and become acquainted with various aspects of clinical psychiatry. The students chosen are Messrs. Charles V. Allen, Robert R. Rynearson, and James William Larson.

Further information on these fellowships may be obtained from the Fellowship committee, P.O. Box 7929, Philadelphia, Pennsylvania.

NATIONAL HEARING WEEK, MAY 5-11

National Hearing Week, sponsored by the American Hearing Society, will be held from May 5-11. In announcing this special week, the American Hearing Society hopes to alert the public to the problems of hearing loss and to the importance of efforts to prevent deafness, conserve hearing, and, when these fail, rehabilitation. It is estimated that there are 15 million hard of hearing persons in the United States, three million of whom are young children. Because impaired hearing is not a "visible" handicap, the average citizen is not aware that nearly one in ten of his fellow Americans suffers from some degree of hearing loss.

In Memoriam

KENNETH E. FRITZELL

Dr. Kenneth E. Fritzell, prominent Grand Forks, North Dakota, surgeon, formerly of Minneapolis, died February 19, 1957, in Boston, Massachusetts, where he had undergone heart surgery. He was forty-nine years old.

Born in Minneapolis, Dr. Fritzell graduated from the University of Minnesota Medical School in 1931. He was a resident fellow in surgery at the University and at Minneapolis General Hospital. He practiced in Minneapolis from 1935 until he entered the U. S. Navy in 1942.

Dr. Fritzell joined the staff of the Grand Forks Clinic following his discharge from service in 1946 with the rank of commander.

He was a member of the staffs of Deaconess and St. Michael's Hospitals in Grand Forks, serving as chief of staff at Deaconess from 1951 through 1954.

He belonged to the North Dakota State Medical Association and the American Medical Association.

Dr. Fritzell had also been a member of the Hennepin County Medical Society, the Minnesota State Medical Association and was on the staffs of Abbott and Northwestern Hospitals in Minneapolis.

BYRL R. KIRKLIN

Dr. Byrl R. Kirklin, retired member of the Mayo Clinic staff, and one of the country's most prominent radiologists, died March 3, 1957, in Rochester. He was sixty-eight years old.

Born in Gaston, Indiana, Dr. Kirklin received his medical education at the University of Indiana College of Medicine. He took postgraduate work in radiology at the Mayo Clinic and joined the staff in 1926. He was named head of the diagnostic roentgenology department in 1930.

He was well known for his work as secretary of the Advisory Board for Medical Specialties and also as secretary of the American Board of Radiology. He served many years as a member of the AMA House of Delegates as a delegate from the Section on Radiology. He served as vice chairman of this section in 1936 and as chairman in 1937.

Dr. Kirklin was a professor emeritus of the University of Minnesota graduate medical school and had served as director of its Division of Radiology. He was also chairman of the Minnesota Advisory Committee to Selective Service for state dentists, physicians and veterinarians.

In addition to his activities in the American Medical Association, Dr. Kirklin was a member of the Zumbro Valley Medical Society and the Minnesota State Medical Association.

He is survived by his widow; one son, Dr. J. W. Kirklin, a heart surgeon at the Mayo Clinic, and one daughter, Mrs. Karl Ladner, Rochester.

the treatment of rib fractures

P&H RIB BELTS

P&H

This new P&H Elastic Rib Belt Provides firm, yet gentle, uniform support with needed compression. The belt is made of a strong elastic band with attached webbing straps and adjustable buckles that do not touch the skin. Far more comfortable and effective than adhesive strapping.

A complete stock of all sizes . . . both male and female are available at all times.

General Interest

The staff of St. Joseph's Hospital, Brainerd, has elected **Dr. William E. Fitzsimons** chief of staff for 1957. Vice chief of staff is **Dr. Helen W. Longfellow**, and **Dr. Arden O. Anderson** was chosen secretary-treasurer.

* * *

Dr. John F. Lewis, Minneapolis, addressed a dinner meeting of the Washington state chapter of the American Cancer Society on February 27, and presented a report on cancer surgery before the American College of Surgeons meeting, February 28 through March 2 at Seattle, Washington.

* * *

Clarkfield is the new address of **Dr. Suad Niazi**, who took over his duties at the clinic there February 4. He has spent the past eight or nine years at University Hospitals, Minneapolis, and Ancker Hospital, St. Paul.

* * *

The *Minneapolis Star* on February 12 carried a colored picture story of the open heart surgery performed at University Hospital by **Drs. C. Walton Lillehei, Richard L. Varco** and others, on a two-year-old French girl brought to the University for that purpose.

* * *

Dr. John J. Bittner, University of Minnesota cancer biologist, was selected as the recipient of the 1957 Bertner Foundation award presented annually by the University of Texas M.D. Anderson Hospital and Tumor Institute, Houston, Texas. The award was presented on March 8, at which time **Dr. Bittner** delivered the Bertner Foundation lecture on "Studies on Mammary Cancer in Mice and Their Implications for the Human Problem." **Dr. Bittner**, who is George Chase Christian professor of cancer research and director of the division of cancer biology at the University of Minnesota Medical School's pathology department, was cited for his "inspirational research on the factors involved in the origin of mammary cancer in mice."

* * *

The March meeting of the Minnesota Academy of Occupational Medicine and Surgery was held at the Calhoun Beach Hotel, Minneapolis, March 12, in conjunction with the Minnesota Occupational Health Nurses. Guest speakers were **Dr. A. E. Ritt** and Miss Cathryn Smith, who talked on "What the Nurses Expect of the Doctor."

* * *

The Minnesota Society of Neurology and Psychiatry held its March meeting at the Town and Country Club in St. Paul, Tuesday, March 12. The scientific program consisted of papers by **Dr. Richard Teeter** on "Body Image and Physician Symptoms," and **Dr. Ian Brown** on "Brain-Liver Relationships."

* * *

Dr. Merrill Chesler was the principal speaker at the February 5 meeting of the Third District Minnesota

Nurses Association held at the Glen Lake Sanatorium. His lecture on "Burn Therapy" was part of a refresher course in preparation for Civil Defense.

* * *

Jasper is the new location of **Dr. Frank Boyd**, who comes to that community to practice after two years spent in Edgerton, Wisconsin. **Dr. Boyd** is a graduate of the Harvard Medical School.

* * *

Dr. John F. Briggs, clinical associate professor of medicine at the University of Minnesota, was the speaker on March 4 at the Groveland Park school, where he addressed the child psychology study unit on "Emotions and Their Effect on the Heart."

* * *

Dr. Fred W. Behmler of Morris, now serving the second half of his four-year term as senator in the Minnesota legislature, is the only physician in that governmental body.

* * *

The community of Gilbert paid tribute on February 3 to **Dr. Moses Strathern**, pioneer doctor in that area. The celebration was held in the First Presbyterian Church, of which **Dr. Strathern** is a long-time elder. He was named as Gilbert's outstanding citizen in 1950, and is a member of the "Football Greats" at the University of Minnesota.

* * *

Dr. C. W. Truesdale, Glencoe, was elected chief of the medical staff at the Glencoe Hospital. **Dr. Arthur Neumaier** was selected as assistant chief, and **Dr. Maurice McNeil** as secretary-treasurer.

* * *

Among the speakers at the short course for internal medicine specialists held at the University of Minnesota's Center for Continuation Study, March 4-6, were **Dr. Max B. Lurie**, Philadelphia, Pennsylvania pathologist, and **Dr. Carleton B. Chapman**, professor of medicine, Southwestern Medical School, Dallas, Texas.

* * *

Dr. Gordon R. Kamman, St. Paul, attended the International Symposium on the Reticular Formation of the Brain, held at the Henry Ford Hospital, Detroit, Michigan, March 14-16.

* * *

Approved residences in Physical Medicine and Rehabilitation are available at the New York University-Bellevue Medical Center, beginning July 1, 1957. American graduates with approved internships are eligible for OVR Fellowship, with a stipend of \$3,400 per year, with an added dependency allotment. Application should be made immediately to **Dr. Joseph G. Benton**, Institute of Physical Medicine and Rehabilitation, 400 East 34th Street, New York 16, New York.

Everybody's Going To Europe . . .

YOU Should Go Round The WORLD!

No, there's nothing fantastic about the idea. You probably need a good vacation—one that will really make you forget the cares of your daily practice. A trip to Europe would be great! But we suggest something even better—the vacation you've always wanted—a wonderful trip **Round the World!**

You'll visit Hawaii, Tokyo, Hongkong, Bangkok, Delhi, Calcutta, Damascus, Cairo, Athens—plus, of course, Rome, Paris, London and all the rest! And you won't have to travel by a slow tramp steamer—instead, you'll FLY!

The cost? Not much more than a trip to Europe. Only \$1995 for 38 glorious days of discovering the most thrilling cities in the world!

FREE HOME CONSULTANT SERVICE

You're a busy man, and planning a trip takes time. To save your valuable daytime hours, one of our experienced tour consultants will work out details of your trip, answer questions for you and your wife, in the privacy of your home—whatever evening you prefer. You will be under no obligation.

Call or write Mr. Egan for free information on Round the World or European travel.

New STEELINE Pediatric Table

*Eases the burden of the
physician's daily work*

Includes built-in tare balance scale, built-in measuring rod, foam rubber cushion and electrical outlets with cord and plug—there are no accessories to buy. Top quality construction features include all-welded steel body, two roomy drawers and a large open compartment with shelf, providing easy, unhampered access to instruments and supplies. Front edge is protected from wear by a stainless steel baffle plate. Despite the fact that this new table has been designed to provide the physician with the best modern equipment, efficient modern production methods in our own factory permit us to keep the price well below that of comparable models. Write today for complete information.

MINNESOTA BLUE CROSS-BLUE SHIELD

The Minnesota Blue Shield Board of Directors has initiated the creation of a Physicians Review Committee of practicing physicians, which will serve the purpose of reviewing unusual claims and making recommendations regarding them.

The Physicians Review Committee is to consist of twelve members, one from each of nine specialty organizations and two from the Minnesota Academy of General Practice, and the President of Minnesota Blue Shield, who will serve as chairman. Each of these organizations has been requested to elect or appoint the member or members and alternate members to serve on this committee.

Other Blue Shield Plans, and the practicing physicians in the areas served by them, have found such committees very effective not only in solving the problems involved in unusual claims but in providing practicing physicians with a broader knowledge and understanding of Blue Shield affairs and activities.

Up to the date of this release, members and alternate members of all but two of the organizations have been elected or appointed and it is anticipated the remaining members and alternates will be selected in the near future. Work of the committee will be started as soon as the full membership has been selected.

January Blue Cross activity resulted in a payment of 99,862 days of hospital care for 16,752 participant subscribers compared to 86,830 days for 14,562 participant subscribers during January, 1956.

While the major part of this increase in utilization is attributable to the increase in the number of contracts in effect, increased incidence rate was experienced in accident care and non-surgical illnesses during January, 1957 compared with January, 1956. These figures might possibly indicate a continuing trend in the increase of accidents among Blue Cross subscribers.

Figures contained in the 1956 annual Blue Cross report reveal that during 1956, 30,069 accident cases were paid compared with 25,524 cases paid during the preceding year.

This increase in cases resulted in approximately \$500,000 in benefits paid for Minnesota Blue Cross subscribers.

MINNEAPOLIS WOMAN SENTENCED TO FOUR-YEAR TERM FOR ABORTION ATTEMPT

Re: State of Minnesota vs. Alida Toivonen

On January 4, 1957, Alida Toivonen, fifty-eight years of age, 416 21st Ave. N., Minneapolis, was sentenced to a term of not to exceed four years in the Women's Reformatory at Shakopee, Minnesota, by the Hon. Levi M. Hall, Judge of the District Court of Hennepin County, pursuant to her plea of guilty to a charge of attempted abortion. The defendant had also entered a plea of guilty to an information charging her with having two prior felony convictions. However, Mrs. Toivonen had indicated to the Court that she desired to leave Minneapolis and go to Hot Springs, Arkansas, to live and Judge Hall therefore stayed the execution of the sentence for a period of four years on condition that she leave the State of Minnesota. Judge Hall gave the defendant five days in which to leave the State of Minnesota and placed her on probation with the Hennepin County Probation Office for the sole purpose of making certain that she left the state within five days. Notwithstanding the fact that the defendant has two prior convictions for abortion, Judge Hall was unwilling to order the defendant to serve her sentence.

The defendant was arrested after the authorities learned that a Golden Valley, Minnesota, mother of a seventeen-year-old-girl had secured the services of Mrs. Toivonen in aborting her pregnant daughter. Although Mrs. Toivonen was paid the sum of \$100.00 for her services, the patient did not abort and she later married the young man who was responsible for her pregnancy.

Mrs. Toivonen has two prior convictions for the crime of abortion. On February 13, 1945, Mrs. Toivonen entered a plea of guilty to an information charging her with that crime and she was sentenced by the Hon. Paul W. Guilford, Judge of the District Court of Hennepin County, to a term of one year in the Minneapolis Workhouse. However, she was released from the workhouse after serving six months of her sentence, when she was placed on probation for eighteen months. On October 7, 1947, Mrs. Toivonen again entered a plea of guilty to an abortion charge before the Hon. E. A. Montgomery, Judge of the District Court of Hennepin County, at which time she was sentenced to a term of not to exceed four years in the Women's Reformatory at Shakopee. However, Judge Montgomery stayed the execution of the sentence and placed the defendant on probation. Mrs. Toivonen, who was born in Yellow Medicine County, Minnesota, on March 8, 1898, holds no license to practice any form of healing in the State of Minnesota. However, she claimed that she had taken a correspondence course in nursing and worked in a small hospital in Wisconsin as a practical nurse.

Surgical Aspects of Coronary Heart Disease

JOSEPH J. GARAMELLA, M.D.
Minneapolis, Minnesota

THE SURGICAL treatment of coronary artery disease perhaps lends itself more to prophecy than to presentation of past accomplishments. Ideally, the ultimate goal and treatment should be the prevention and/or reversal of the arteriosclerotic process. Unfortunately, this goal does not appear to be within immediate grasp. A further understanding of immunologic processes may permit the transplant and substitution of whole organs such as the heart. Recent advances in extracorporeal heart-lung apparatuses and elective cardiac arrest may render surgery on the coronary vessels such as endarterectomy and direct anastomoses, more practical. The future appears promising but nevertheless does not fulfill the current need for a surgical method of treating the nation's number one killer.

Incidence and Prognosis.—According to the statistics of the United States Public Health Service¹ 373,597 persons died of arteriosclerotic heart disease in 1953, the most common cause of death in the United States. This figure exceeded that for deaths due to cancer, the second most common cause of death, by more than 100,000. Approximately every ninety seconds, death due to coronary disease occurs in the United States, a nation whose population roughly comprises one-sixth of the world population.

The mortality rate in acute coronary occlusion is between 15 and 25 per cent. Life expectancy after recovery varies greatly, and the average duration of life is said to be about three to four years.² According to Silber and Katz,³ of those surviving the initial attack, 50 per cent survived

five to twenty years and three-fourths of these lived ten to twenty years. Stated differently, 50 per cent of those surviving the initial attack succumb in five years and 62.5 per cent in ten years. The potential malignancy of the disease is apparent.

Historical Aspects of Surgical Treatment.—In 1916 Jonnesco⁴ on the basis of speculative reasoning of Francois Franck⁵ performed bilateral stellate ganglionectomy to relieve angina. Since that time numerous other experimental and clinical methods have undergone trial and fundamentally these fall into the following categories:

1. Nerve interruption
2. Reduction of basal metabolism
3. Development of collateral circulation by vascular grafts
4. Development of collateral circulation from cardio-pericardial adhesions
5. Development of existing anastomotic channels
6. Local resection of pathologic lesions

A discussion of the various surgical methods is not within the scope of this presentation.

Evaluation and Interpretation of Results.—One of the barriers to the acceptance and clinical application of experimental methods has been the inconstancy of results reported by various investigators relative to the principal test method, coronary artery ligation with comparison of mortality and infarcts in control and test animals. Considering the multiple variables in such an operative procedure, this variation in results is not difficult to understand. Furthermore, the application of test procedures to normal animal hearts rather than hearts with varying degrees of chronic occlusion which simulate human heart disease has been offered as a criticism of experimental studies. Our own experiments following acute and chronic oc-

From the Jay C. Phillips Research Laboratory, Mount Sinai Hospital and Department of Surgery, University of Minnesota, Minneapolis, Minnesota.

Supported in part by grants from the Minnesota Heart Association, American Heart Association, and the Cardiac Research Committee, Minneapolis, Minnesota.

clusion⁶ have demonstrated, in terms of coronary arteriography in the intact animal and peripheral coronary pressures distal to occluded points, that the development of collateral coronary circulation

vessels, the physiologic need produced by coronary artery occlusion is removed by the intercoronary collateral circulation. These data, however, may not apply during periods of cardiac strain.

Modified Cardiopneumopexy Employing Segmental Resection

Fig. 1. Schematic representations showing variations of segmental resection and segmental cleavage for modified cardiopneumopexy.

Modified Cardiopneumopexy Employing Segmental Resection, Arterialization and Venous Obstruction

Fig. 2. Schematic representations of segmental resection for modified cardiopneumopexy combined with aorticopulmonic anastomosis and with pulmonary vein obstruction.

Fig. 3 (a) and (b). Heart-lung specimens following modified cardiopneumopexy with segmental resection showing the left lower lobe (lower right) fixed to the myocardium. Cannulae and tubing were used for injection studies. (c) Bivalved heart-lung specimen following modified cardiopneumopexy with segmentectomy showing firm union between the structures. Cannulae and tubing were used for injection studies.

soon restores the pressures in the occluded coronary arteries to levels equal to those of unoccluded neighboring arteries. Thus, regarding pressure gradients between coronary and extraordinary

Modified Cardiopneumopexy Employing Pulmonary Segmental Resection.—Of the many experimental and clinical studies regarding augmentation of the coronary blood supply, the protective

benefits of cardiopneumopexy as reported by Lezius⁷⁻¹⁰ following the concept of Beck¹¹ were among the most outstanding. Experimental and clinical cardiopneumopexy has been reported by others.¹²⁻¹⁸

With the concept that the broad, vascular surface of one or more segments of the lung applied to the heart might provide greater protective bene-

Air-Saline Injection

Fig. 4. Schematic drawings showing results of air-saline injections in heart-lung specimens following modified cardiopneumopexy with segmental resection. (a) Injection into the pulmonary artery shows fillings of coronary arteries and coronary veins with emptying into the aorta, coronary sinus and pulmonary vein. (b) Injection of the coronary artery shows filling of pulmonary arteries and veins and coronary sinus.

Directional Flow Study

Fig. 6. Schematic drawing of experimental arrangement for directional flow study. Catheter attached to perfusion bottle is threaded through upper lobe artery to distribution area of left lower lobe previously treated by segmental resection and grafted to myocardium. The inferior pulmonary vein is diverted to a beaker at level of left atrium. A Heidenhain suture for obstruction of bronchial vessels is placed around the lower lobe bronchus. The perfusion is then conducted in two stages without and with coronary artery occlusion.

Fig. 5 (a). Heart-lung specimen obtained from animal dying on seventh postoperative day following cardiopneumopexy with bilateral segmentectomy through transverse sternotomy. Cause of death was atelectasis and empyema. Injection of contrast media into pulmonary artery shows filling of coronary arteries and coronary veins. Failure to cannulate one tributary of the inferior pulmonary vein allowed reflux filling of the left atrium and right pulmonary tree. (b) Heart-lung specimen 41 days following cardiopneumopexy with segmental resection of left lower lobe. Injection of contrast media (sodium Hypaque) into pulmonary artery shows filling of coronary arteries and veins. Cannulae in coronary sinus (left side) and in pulmonary vein (right upper corner) also contain dye.

fits to the ischemic heart than the previously described methods of cardiopneumopexy, various combinations of pulmonary segmental resection and segmental cleavage have been explored experimentally with and without arterialization and venous obstruction of the grafted lobe (Figs. 1 and 2). Excellent heart-lung union was a constant feature of the operations (Fig. 3a, b, c) and anastomoses between the heart and the lung were consistently demonstrated by injection studies (Figs. 4 and 5a, b). Directional blood flow studies were performed in twenty animals previously prepared by modified cardiopneumopexy with segmental resection and segmental

Directional Flow Study

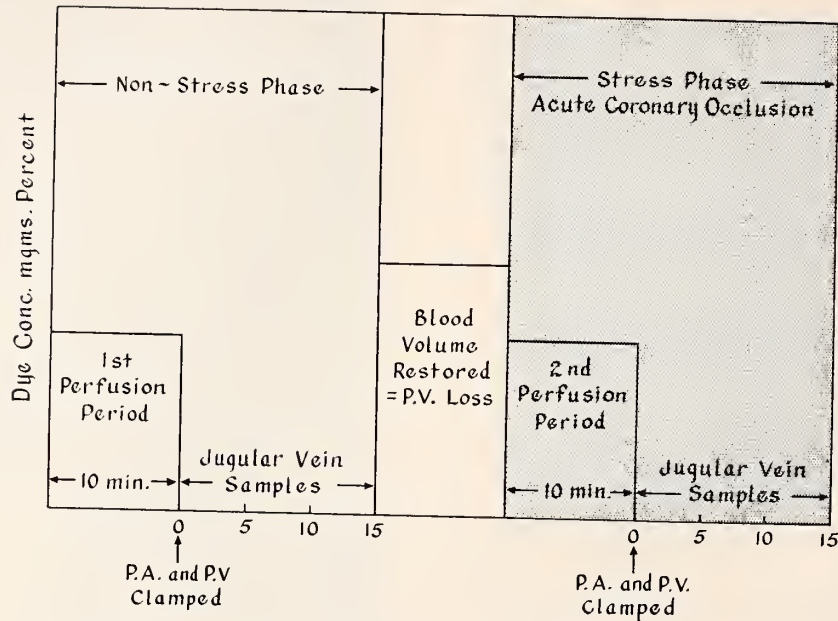

Fig. 7. Scheme of sequences in directional flow study. In the first perfusion period, nonstress phase, 100 to 125 cc. of citrated whole blood containing 5 cc. of Evan's blue dye is dripped into the pulmonary artery of the grafted lung over a 10-minute period. The pulmonary artery and pulmonary vein are then cross-clamped in order. Jugular vein samples at five-, ten- and fifteen-minute intervals are drawn. The animal's blood volume is restored. The second perfusion period, stress phase with acute coronary occlusion, is conducted as in the first phase and jugular vein samples are repeated.

Fig. 8a.

Figure 8 (a). Following perfusions, blood samples from jugular veins are centrifuged and dye content concentrations of plasma are read from a spectrophotometer. Graph above shows results of four consecutive directional flow studies. Number 508 shows an appreciable amount of dye in the first phase, but nevertheless, an increase in the second phase. The cause for dye in the first phase was not determined. Possibilities are technical error with reflux of dye into systemic circulation and dependency on extracoronary source of blood without coronary occlusion. Studies 509 and 512 show

Fig. 8b.

essentially no dye from systemic blood samples taken in the first, nonstress, phase, whereas, in the second phase with acute coronary artery occlusion there is a significant rise in dye concentration. Number 514, a control study without cardiopneumopexy, shows negligible amounts of dye following both phases of perfusion. (b) Dye concentrations of systemic blood samples following perfusion studies. Numbers 529 and 538 show small concentrations of dye during the first phase of perfusion with a significant sharp increase when acute coronary occlusion is present. Number 533, a control study, shows essentially no dye in both phases.

cleavage (Figs. 6 and 7). On the basis of dye studies of systemic blood samples following perfusion of the grafted lobe (Figs. 8a, b), it appears that blood from an extracoronary source, grafted lung in our studies, flows into the normal coronary circulation in small increments and is significantly increased when acute coronary occlusion is induced. The data support the feasibility of augmenting the coronary circulation by an extracoronary blood supply. Details of the surgical technique of this modification of cardiopneumopexy with pulmonary segmental resection, injection studies and directional flow studies have been described previously.¹⁹

Subsequent mortality-infarct studies have shown that modified heart-lung graft provides significant protection against coronary artery ligation. The details of these experiments and the follow-up studies of surgically treated patients will be the subject of a later report.

PROFESSIONAL LIABILITY SUBJECT OF NEW FILM

The second film in the AMA-American Bar Association series on "Medicine and the Law" will deal with prevention of professional liability action, it has been announced. Titled "The Doctor Defendant," the film will be available from the AMA Film Library for medical society or association showings, beginning July 1.

The new film dramatically presents four case reports of situations which caused legal action against physicians. In reviewing these alleged mal practice cases, the thirty-minute black and white sound film also demonstrates how a professional liability committee functions. It will be premiered at the AMA convention in New York City on June 5.

"The Doctor Defendant" is a companion film to "The Medical Witness" in the series produced by The Wm. S. Merrell Company, Cincinnati, O., ethical phar-

maceutical laboratories, in cooperation with the AMA and the ABA, as a service to the medical and legal professions.

"The Medical Witness" depicts right and wrong methods of presenting medical testimony by re-enacting a personal injury trial. It was named by *The New York Times* as one of the best 16 mm. films produced in 1956. A thirty-minute black and white sound film, it was also selected by the Golden Reel Film Festival as one of the five best films on professional education.

Societies desiring to show either or both films may write to the Film Library, American Medical Association, 535 No. Dearborn Street, Chicago 10, Illinois, or to Dr. John B. Chewning, director of professional relations, The Wm. S. Merrell Company, Cincinnati 15, Ohio.

Benign Tumors of Peripheral Nerves and Their Masquerade

HENRY W. DODGE, JR., M.D.
WINCHELL McK. CRAIG, M.D.

Rochester, Minnesota

THE OCCURRENCE of tumors of peripheral nerves is infrequent enough in the lifetime of the individual physician to limit his practical knowledge and experience. Despite the considerable amount of attention and interest devoted to these tumors, the pertinent literature has concerned itself mainly with origin and pathologic classification; thus, the casual reader with little neurosurgical or neuropathologic interest may have undergone only slight exposure to the clinical manifestation of these tumors.

General Background

Although much has been written about tumors of peripheral nerves, final incontrovertible proof of their cause has yet to be demonstrated. Therefore, we have chosen to refer to these tumors as "neurofibromas," or "neurilemmomas." The term "neurofibroma" is a time-honored, generally understood label. "Neurilemmoma" appears to be the least objectionable of the remaining alternate terms, such as schwannoma, perineural fibroblastoma, neurinoma, peripheral glioma, neuroma and schwannoglioma, for it does not connote embryonic derivation of tissue.

Since the literature on tumors of peripheral nerves is concerned primarily with the rather technical aspects of etiology and cellular derivation, only some of the more prominent contributions will be mentioned. Tumors of peripheral nerves were referred to by the ancients as "nodes" or "ganglions." Cheselden¹ stated that a neural tumor had been removed in 1773. However, Odier² generally is credited with priority (1803) in this subject. Smith,³ Virchow,⁴ von Reckling-

hausen,⁵ Verocay,⁶ Thompson⁷ and Antoni⁸ contributed importantly to knowledge of these lesions prior to 1920. Since 1920, the names of Masson,^{9,10} Foot,¹¹ Penfield,^{12,13} Bailey,¹⁴ Geschickter,¹⁵ Tarlov,¹⁶ Nageotte,¹⁷ Stout,¹⁸ Murray,¹⁹ Lhermitte²⁰ and Cohn,²¹ as well as other authors,²²⁻²⁴ have figured prominently in writings on tumors of peripheral nerves.

Present Study

We have studied a total of 343 solitary benign tumors of the sheaths of peripheral nerves that were removed surgically at the Mayo Clinic between 1909 and 1948, inclusive. All peripheral nerves were included in this study except the intracranial portions of the cranial nerves, the optic nerves, the spinal nerve roots and the sympathetic nervous system.

In an attempt to obtain a clearer picture of the true nature of these so-called benign tumors of nerve sheaths, we have excluded traumatic, amputational, sclerosing or diffuse plexiform neuro-
mas, metastatic, malignant or multiple tumors, and any lesions possibly related to Recklinghausen's disease.

The pathologic diagnosis was made routinely from fixed sections stained with hematoxylin and eosin. Special stains for reticulin, connective tissue, neurofibrils and fat were employed in some cases.

Report of Cases

During the course of this review of 343 benign tumors of peripheral nerves, we were impressed by the interesting masquerade with which these tumors occasionally may mimic other commonplace disorders. Reports of seven cases will be presented to illustrate this deceptive masquerade. Such lesions may be discovered if the possibility of these rather uncommon tumors is kept in mind.

One of the most interesting groups of tumors of peripheral nerves includes those lesions asso-

Abridgment of thesis submitted by Dr. Dodge to the Faculty of the Graduate School of the University of Minnesota in partial fulfillment of the requirements for the degree of Master of Science in Neurosurgery.

From the Section of Neurologic Surgery, Mayo Clinic and Mayo Foundation.

The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

ciated with pain in an extremity that simulate other clinical conditions; these tumors are found only by careful examination. Sciatic pain and pain in the lower part of the back usually are attributed to a lesion within the spinal canal such as a protruded intervertebral disk or intraspinal tumor, to constitutional disorders such as diabetes or gout, or to changes in the bony structure of the lumbosacral vertebrae, such as occur with osteoarthritis, trauma or strain. The following two cases illustrate how important it is to examine the peripheral nerves for evidence of tumor, even in patients with good "disk" stories.

Case 1.—A fifty-year-old man came to the clinic because of severe pain involving the entire right leg. He had slipped and fallen on a wet concrete slab, striking the right hip. Subsequently, he noticed soreness in the right ankle and lower leg; pain gradually ascended over the anterior and lateral aspects of the leg to the upper part of the thigh, the sciatic notch and into the hip. The pain was intermittent at first, simulating that of a disk syndrome. For three months previous to examination, the pain had been constant both day and night but worse at night, suggesting an intraspinal tumor. The muscles in the posterior part of the thigh and leg were tender.

Examination at the clinic disclosed weakness of the muscles of the entire right lower extremity without any sensory changes. A small nodule could be palpated in the middle third of the thigh in the region of the sciatic nerve. Pressure on this nodule produced excruciating pain both above and below the distribution of the sciatic nerve.

A midline incision was made on the posterior aspect of the middle third of the right thigh, and a neurofibroma measuring 2 cm. in diameter was found imbedded in the peroneal division of the right sciatic nerve. The tumor was carefully dissected free and removed. After operation, the patient was completely relieved of pain.

Case 2.—A forty-one-year-old woman came to the clinic because of pain in the lower part of the back and the left leg. This had been present for ten years, first occurring when she was six months' pregnant. Pain in the leg had been present intermittently for the next five years, when a dull ache appeared in the left popliteal space associated with a cramping sensation in the left leg. This type of pain continued intermittently for three years, after which she noticed intermittent sharp pain shooting from the dorsum of the left foot to the inside of the leg and extending into the back. Weakness of the muscles of the entire left leg was present, but sensory loss was not apparent. Some atrophy was evident. The patient had been diagnosed as having a protruded intervertebral disk but results of examination of the cerebrospinal fluid were negative.

Examination revealed a small nodule on the sciatic

nerve. A small neurofibroma measuring 18 by 15 by 12 mm. was removed surgically from the inner portion of the left thigh. The tumor appeared to be attached to the femoral nerve and to a branch of the anterior cutaneous or saphenous nerve. The patient was completely relieved of pain after this operation.

Another interesting example of the obscure masquerade that a peripheral-nerve tumor sometimes may effect is well demonstrated in Case 3.

Case 3.—A fifty-two-year-old man came to the clinic because of a two and one-half year history of pain and unusual sensations in the left leg. Pain in the medial aspect of the left thigh had commenced initially after the patient had bumped his left shin at a ball game. Two months later, he had experienced numbness of the medial aspect of the left knee and medial surface of the thigh. Six months later, the patient noted loss of strength in the left quadriceps muscle, which would cause him to fall on occasions. Severe paroxysms of pain lasting two or three hours began later in the medial aspect of the left knee, occurring most often at night. Narcotics were necessary to control the severe pain.

During the two-year period prior to registration at the clinic, the patient had various "septic foci" (teeth, tonsils, sinuses) removed or drained. He had tried applications of moist heat, physiotherapy and traction on the leg and had visited many warm-water spas with only transient relief. Absolute alcohol had been injected into the anterior crural nerves on the left. The cerebrospinal fluid had been considered to be normal. Exploratory lumbar laminectomy and rhizotomy had been done but to no avail.

Two months before consultation at the clinic, while hospitalized for pain, the patient had felt a mass in his left groin. Subsequent roentgen therapy had produced no effect on the pain.

Examination at the clinic revealed a firm, movable, tender tumor about 10 cm. in diameter in the left lower abdominal quadrant. The left thigh was smaller than the right and the left quadriceps muscle was paralyzed. Patellar and cremasteric reflexes were absent on the left.

Laparotomy revealed a neurofibroma measuring 20 by 12.5 cm. that was attached to the left femoral nerve. Removal of this tumor gave relief of symptoms.

A rather unusual cardiac masquerade occurred in Case 4.

Case 4.—A fifty-one-year-old man had been in excellent health until April, 1943. During a card game at that time, he noted a dull aching pain to the left of the sternum and a sharp shooting pain down the upper left arm. Shortness of breath was present for about an hour.

An electrocardiogram made several days later was considered normal. However, because of the patient's concern about a "heavy sensation" in the left precordium, he was advised to take a month's vacation. After the first few days of vacation, he again experienced dull aching pain in the left side of the thorax, and at times

he noticed a choking sensation in his throat. The precordial pain was induced by such factors as nervousness, fear, walking or fatigue. Two or three hours of work at his ordinary occupation caused the precordial distress to return and necessitated rest. The pain was relieved by rest and lying down and was better when he was not under nervous tension.

Careful examination at another clinic, which included thoracic roentgenograms that we reviewed later, suggested the diagnosis of mild coronary angiospasm. Rest, sedation and subsequent examinations were advised.

In January, 1944, because the patient was unable to lie on his left side, another thoracic roentgenogram was taken. A rounded mass was recognized at the right cardiophrenic angle and the patient was referred to the clinic.

Examination and stereoscopic thoracic roentgenograms at the clinic confirmed the presence of the mass. A benign neurofibroma measuring 9 cm. in diameter that had arisen between the ninth and tenth ribs was removed surgically from the posterior mediastinum on the right. The postoperative convalescence was uneventful and the patient was completely relieved of his symptoms. Evidence of cardiac disease could not be found.

Complaints of pain and disability involving the neck, shoulder and upper extremity are so common that the examining physician may overlook peripheral-nerve tumors as he considers the possibility of such entities as cervical hypertrophic arthritis, tumor of the cervical portion of the spinal cord, myelitis, protruded cervical intervertebral disk, posttraumatic brachial neuralgia, cervical rib, scalenus anticus syndrome, bursitis and angina pectoris.

Careful palpation of the involved parts may be exceedingly helpful, as shown in the following case, which typifies the problems present in many patients who have benign tumors of the cervical and brachial plexus.

Case 5.—A sixty-six-year-old man who had severe essential hypertension was first examined at the clinic in March, 1933, because of a two and one-half year history of pain in the left arm. Initially, the patient had begun to notice occasional sharp shooting pains in his left arm and a sore neck. He had not sustained any injury to his neck. These pains often were accompanied by a feeling of tingling and numbness in the fingers. After the patient used his left arm for a few minutes, he would note the onset of a dull ache, which was most severe in the region of the elbow. During this period, the patient had several episodes of epistaxis apparently related to the hypertension.

The sharp shooting pains, dull ache and tingling paresthesia were all accentuated when the patient lay down. When standing erect, he obtained considerable relief from the discomfort. Coughing, sneezing and straining greatly increased the pain, as would flexion and

extension of the neck and turning the head. Precordial distress had not been present.

Various forms of treatment had been tried but only intermittent relief had been obtained. The pain and discomfort had become gradually worse during the year before registration at the clinic. Multiple examinations had been unrewarding as to the cause of the pain. His ability to earn a living was becoming seriously affected and he had become rather concerned.

Just before the patient came to the clinic, the home physician had noticed a small lump in the left side of the neck. Roentgen therapy to this region had not produced any effect on the symptoms.

Examination at the clinic confirmed the presence of a nodule in the left supraclavicular fossa. A benign neurofibroma was removed surgically from one of the branches of the left brachial plexus. Recovery was uneventful and the patient obtained complete relief from his distressing symptoms.

Another intriguing masquerade was that of "renal colic" in Case 6.

Case 6.—A twenty-two-year-old woman was first examined at the clinic in April, 1945, because of a three-year history of pain in the left flank extending to the left thigh. The patient had bumped into the corner of a table, striking her abdomen. Several months later, she had noted the onset of pain in her left flank. This pain extended down the anteromedial aspect of the left thigh; it was severe and paroxysmal, occurring once or twice a month and being helped sometimes by complete rest in bed. More often than not, however, morphine was required for relief.

One month prior to admission, the patient had been bedridden for twenty-two days as the result of severe pain and tenderness in the left flank, extending to the anteromedial aspect of the left thigh. Straining and coughing accentuated the distress, as did even the slightest motion in bed; morphine was required. Pain was absent at night. The patient had noted blood in her stools previously and had been treated for amebiasis. A mild vaginal discharge had been present; the menses were normal and there was no evidence of urinary dysfunction.

A diagnosis of kidney stone, "floating kidney" or renal tumor had been made elsewhere. Just prior to the patient's admission to the clinic, the suggestion that a tumor of the spinal cord might be the basis of her trouble prompted the patient to seek outside opinions.

Examination at the clinic revealed slight diminution of sensation over the first and second lumbar dermatomes. Examination of cerebrospinal fluid showed no abnormalities. Excretory and retrograde urograms and roentgenograms of the abdomen and pelvis indicated normal conditions in the upper part of the urinary system. A round shadow of increased density appeared over the psoas muscle in the left lower quadrant.

A benign neurofibroma measuring 6 by 5 by 6 cm. was removed surgically from the extraperitoneal paravertebral space on the left; the tumor apparently arose

from a branch of the left lumbar plexus. The postoperative convalescence was uneventful. A minimal postoperative neurologic deficit remained. The distressing symptoms were completely relieved.

Case 7.—A fifty-nine-year-old man was referred to the clinic for evaluation of Bell's palsy on the left side of his face. Six months previously, the patient had been driving his car with the window open and the wind blowing on his face. He felt later as though he had "caught cold" in his face. His face felt "heavy" the next morning and he noted that speech was difficult. Looking in the mirror he recognized that his face was completely paralyzed on the left side.

A diagnosis of typical Bell's palsy was made and he was told that treatment was not necessary except perhaps to massage the face and to attempt voluntary innervation of the left facial musculature. After six months had passed with no signs of return of function, the patient was referred to the clinic.

Our examination showed complete palsy of the peripheral portion of the left facial nerve. No history of headache, visual disturbance, pain, diminished facial sensation, tinnitus, reduced audition, dizziness or staggering gait could be elicited. The optic rotations were normal. Fundusoscopic examination disclosed normal optic nerves. Careful palpation along the peripheral course of the left facial nerve revealed a small, moderately firm nodule just distal to the emergence of the nerve from the stylomastoid foramen.

A small benign neurofibroma was enucleated surgically from the facial nerve.

A number of patients dated the onset of their trouble to some traumatic incident. It is difficult to know whether the accident merely helps to fix the time of events in their life or whether trauma in certain cases may precipitate symptoms as the result of edema or hemorrhage in the unsuspected tumor. Trauma itself, however, would not appear to play an important role in the causation of these tumors.

Symptoms

The shortest duration of symptoms recorded in our 343 cases was several days and the longest span was thirty-eight years. Neurofibromas (neurilemmomas) of general distribution had an average duration of symptoms of 4.7 years. Tumors arising in the thoracic cavity had an average duration of symptoms of 3+ years; however, the majority (twenty-nine cases) of the thoracic tumors were asymptomatic and were discovered accidentally during routine roentgenography of the thorax.

Females predominated slightly over males, 183 to 160. The youngest patient was a three and one-half-year-old girl who had an asymptomatic

tumor of the thorax. The oldest patient was an eighty-one-year-old man with a tumor of the ulnar nerve whose complaints were of only several months' duration.

Fig. 1. Age distribution of patients with benign peripheral-nerve tumors.

More than half (219 cases) of the lesions occurred in the age groups between thirty-one and sixty years. The greatest number of tumors (ninety-one cases) occurred in the age group between forty-one and fifty years. At the extremes of age, five patients were in the first decade of life and six patients were more than seventy years of age (Fig. 1).

The commonest symptoms or complaints in order of frequency in our series were a lump (tumor, nodule or mass), pain and paresthesia. Pain, although frequent, was not a particularly outstanding complaint. Tumors occurring near vital structures in cramped quarters, such as the neck, gave symptoms due to impingement of the mass on neighboring anatomic structures. Lesions in the thorax and abdomen often were symptomatically silent. Other symptoms are summarized in the accompanying table.

That the symptoms caused by these tumors are well explained by the slow expansion of a soft mass already has been adequately described in the literature. Little emphasis has been placed on the rather startling symptoms that may be caused by the growth of this exceedingly benign tumor in restricted quarters (head and neck), as mentioned previously.

The minimal symptoms produced by relatively enormous intrathoracic neurofibromas (neurilemmomas) emphasize the importance of routine

TABLE I. FINDINGS IN 343 CASES OF BENIGN
TUMORS OF PERIPHERAL NERVES

Mass	224

fashion, slowly growing and exhibiting few objective motor or sensory symptoms, the diagnosis of a benign tumor of a peripheral-nerve sheath should be strongly suggested. Likewise the presence of a large, silent, rounded mass found roentgenologically in the posterior part of the mediastinum should bring to mind the common occurrence of benign neurofibromas in this part of the body.

A slowly or rapidly growing tumor of a nerve causing undue pain and discomfort and showing early motor and sensory disturbances may not be a benign neurofibroma (neurilemmoma). This is particularly true if the patient shows evidence of Recklinghausen's disease; the literature records an 8 to 15 per cent incidence of sarcomatous degeneration in such tumors.²⁵

Fig. 2. Anatomic distribution of 343 benign peripheral-nerve tumors.

roentgenograms of the thorax and underline the important service being performed by mass survey units in the United States.

The paucity of sensorimotor defects in our series, even when a large tumor involved a specific nerve trunk, is rather characteristic and has been well documented previously.

It may be difficult to diagnose those tumors located deeply or in silent zones. Subcutaneous tumors not associated with nerve trunks (and in the absence of Recklinghausen's disease) also are more difficult to diagnose correctly. However, when one discovers along the course of a nerve a lump that is soft, occasionally transilluminable, freely movable laterally but not in a longitudinal

Pathology

Microscopic studies proved that the tumors were neurofibromas. Some of them presented the picture of cells arranged in parallel fashion, the nuclei of which, standing adjacently, formed nuclear palisades. These cells resembled Schwann's cells. Other tumors were made up of more collagenous or loose myxoid tissue with little tendency toward nuclear palisading. Their appearance was more like that of connective tissue. So many gradations occurred between these two types that the extreme difficulty in determining the etiologic factors by histologic methods is apparent. Less and less attention has been paid recently to the Antoni type A and B tissue described so commonly in the literature.⁸

The gross appearance of these tumors is well known. Neurofibromas may be encountered in all parts of the body; in our series, the tumors oc-

removal if feasible. Those lesions subjected to roentgen therapy prior to surgical excision showed little effect from the irradiation.

Fig. 3. Surgical approach to benign tumors located on various portions of the brachial plexus.

Fig. 5. Operative incisions for the approach to benign tumors of nerves of the upper extremity. *a.* Median nerve. *b.* Ulnar nerve.

curred most frequently on the head and neck, on the lower extremities and in the thorax (Fig. 2).

Treatment

Treatment of benign tumors of peripheral-nerve sheaths is entirely surgical. Such tumors, particularly those occurring near vital structures, should be totally excised; however, enucleation may suffice if the lesions occur in important motor nerve trunks. Surgical excision alone has been adequate for recurrent neurofibromas (neurilemmomas) in this series. In the presence of Recklinghausen's disease, careful attention should be paid to total

Fig. 4. Operative incisions for the approach to benign tumors of nerves of the upper extremity. *a.* Musculocutaneous nerve. *b.* Radial nerve.

Fig. 6. Operative incisions for the approach to benign tumors of nerves of the lower extremity. *a.* Sciatic nerve. *b.* Common peroneal nerve.

Tumors of nerves located in the head and neck or in the thorax or abdomen are approached through standard surgical incisions employed in

routine operative procedures in these respective regions.

Based on experience during World War II with injuries to major peripheral nerves and on sug-

Fig. 7. Enucleation of a benign tumor from between the fibers of a major nerve trunk.

gestions from our plastic surgical colleagues, it has been our practice to approach benign tumors of the brachial plexus and of major nerves of the upper and lower extremities by means of the incisions and modifications of the incisions pictured in Figures 3 through 6. Postoperative discomfort because of scars and deformity or limitation of motion in extremities may be considerably lessened by use of such incisions. In addition, attention paid to lines of major cutaneous stress (Langer's lines) accelerates healing of the wounds and promotes a smoother convalescence.

In dealing with a tumor of a major nerve trunk, surgical exigency may force the surgeon to choose between enucleation (if feasible) and excision with primary end-to-end anastomosis of the cut ends of the nerve (Fig. 7). Tumors of sensory nerves do not present the surgical problems encountered in tumorous involvement of a major motor nerve. Many of these benign tumors fortunately may be enucleated rather satisfactorily. If possible, complete removal of the capsule of the tumor is a prerequisite. It is unfortunate to produce an extensive motor deficit during removal of a benign lesion and this should be avoided if possible.

If excision and end-to-end anastomosis are advisable, strict aseptic technique must be employed. Adequate mobilization of the proximal and distal segments of the nerve is a necessity; however, the longitudinal and lateral blood supply to the nerve

trunk should be paramount at all times in the surgeon's consideration.²⁶

It is our practice after excision of the tumor to excise cleanly the cut ends of the nerve with a sharp scalpel or razor blade and to repair the nerve with 00000 interrupted black arterial silk sutures. Advantage may be taken of length gained through mobilization and transplantation and by means of flexion of joints to compensate for neural defect after excision of a tumor. Considerable care should be exercised in the attempt to approximate major bundles within the nerve during anastomosis. The line of sutures in the nerve is not wrapped or covered. After approximation of the adjacent tissues, the wound is closed by means of plain catgut or silk sutures in the subcutaneous tissues and interrupted black silk sutures in the skin.

An involved joint may be immobilized through the use of a sling, posterior molded splint or plaster cast for several weeks after operation. Early graded physiotherapy is instituted, usually in the latter part of the first week after operation. Antibiotics are routinely employed prophylactically beginning the evening prior to operation; their use is maintained until the cutaneous sutures are removed.

Recurrence

The longest postoperative follow-up of a patient was thirty-five years. A total of fourteen patients were treated subsequently for local recurrence of the tumors. Several had recurrence on multiple occasions; the maximal number of episodes of recurrence before cure was attained was three. The recurrence rate is not known for those patients who were not seen again subsequently. Two patients are known to have died from sarcoma developing at the site of previous incision; one other may have had sarcoma.

Summary and Conclusions

Solitary peripheral neurofibromas (neurilemmomas), in the absence of the stigmas of Recklinghausen's disease, apparently are extremely benign lesions that may masquerade deceptively as other pathologic conditions.

These tumors most commonly are evidenced by the presence of a mass along the course of a nerve, but if they occur in deeper tissues or in the thorax or abdomen they may be "silent" and an accurate diagnosis may be delayed or difficult.

Treatment of neurofibromas is always surgical and removal can be effected through excision or capsular enucleation. Recurrence is uncommon, as is malignant sarcomatous degeneration. Roentgen therapy does not appear to be effectual, and trauma apparently is unrelated to the occurrence of these tumors. Advantage should be taken of Langer's cutaneous lines and of "step" incisions crossing flexion creases in planning the operative approach. The prognosis should be excellent after adequate enucleation or total excision.

PROFESSIONAL NURSING SCHOOL ADMISSIONS DECLINE

The number of new students entering schools of professional nursing dropped last year, while admissions to schools of practical nursing remained steady, according to announcement by John H. Hayes, chairman, Committee on Careers, National League for Nursing.

Schools of professional nursing in the United States and territories last year enrolled 45,839 new students, as against 46,498 the previous year. This was the first year since 1952 that admissions to these schools declined and thus failed to keep pace with the steady growth of the college age population.

Practical nursing programs, which are usually one-year nursing courses offered by hospitals, community agencies and vocational schools, admitted some 15,500 new students in the academic year, 1955-56, a number

close to the previous year's admissions.

Students graduated last year from schools of professional nursing totaled 29,591; practical nursing programs prepared about 10,500.

Mr. Hayes advised nursing schools and state and local groups concerned with recruiting students for a nursing career to study their own admission policies, educational programs, scholarship aids and other factors influencing students in choosing a nursing career.

The college or university programs offering a baccalaureate degree, which are four-year to five-year college programs with a major in nursing, admitted 7,145 new students, compared with 6,985 in 1955, indicating a continuation of the growing interest in college and university education for a nursing career.

Sensitization to Blood Antigens in Rh Positive Patients

G. ALBIN MATSON, PH.D.
HELEN ARNDT, M.T. (ASCP)
JANE SWANSON, M.T. (ASCP)

Minneapolis, Minnesota

NUMEROUS cases of sensitization to the less commonly known hereditary blood antigens have been investigated at the laboratories of the Minneapolis War Memorial Blood Bank. These cases are of particular interest because the sensitizations occurred in Rh₀ (D) positive persons in whom physicians usually do not expect sensitization.⁸

The following six cases will illustrate typical problems involving antibodies other than anti-Rh₀ (anti-D).

Case 1.—Sensitization of Rh Positive Rh₁ (CDe) Patient with Production of Anti-rh" (anti-E)¹¹.

Clinical Data.—C. J., aged thirty, a Puerto Rican, the mother of three living children, was group O, Rh positive. She was unable to give a clear history, as she did not speak English. On March 16, 1955, during her first trimester of pregnancy, she was hospitalized for surgical repair of bilateral dislocation of the hips. One 500-cc. unit of blood was administered. On May 11, she received 3 units of O, Rh₀(D) positive blood with no reaction. On May 18, 250 cc. of O, Rh positive blood was given (blood No. 394). The patient reacted with chills and fever. On May 27, 100 cc. of O, Rh positive blood was given (blood No. 433); this was also followed by a reaction. On May 28, 100 cc. of O, Rh positive blood (blood No. 435) was given followed by a hemolytic reaction. On July 8, a sample of the patient's blood was referred to the War Memorial Blood Bank for study. On October 19, 1955, the patient was delivered of an erythroblastotic female infant.

Laboratory Findings:

May 18—Post-transfusion bilirubin 1 min. 1.0 mg. per 100 cc.
Total 2.7 mg. per 100 cc.
Post-transfusion plasma hemoglobin 81.0 mg. per 100 cc.
May 28—Post-transfusion plasma hemoglobin 166.0 mg. per 100 cc.

Serological Findings:

Blood group of patient:
O, Rh positive: Genotype R₁R₂ (CDe/cde)
Blood group of donor No. 394:
O, Rh positive: Genotype R₁R₂ (CDe/cDE)

From the Minneapolis War Memorial Blood Bank.

Blood group of donor No. 433:

O, Rh positive: Genotype R₁R₂ (CDe/cDE)

Blood group of donor No. 435:

O, Rh positive: Genotype R₁R₂ (CDe/cDE)

The patient's serum contained an antibody against the rh" (E) antigen. The titer was 1:1 in saline, 1:8 in 20% albumin media, and 1:8 by the indirect anti-globulin (Coombs) test. The titer was repeated in September and found to be 1:8 in albumin and 1:16 by the indirect Coombs test.

Blood group of the husband:

O, Rh positive: Genotype R₂R₀ (cDE/cDe)

Blood group of twelve-year-old sib:

O, Rh positive: Genotype R₂R₂ (cDE/cde)

Blood group of eight-year-old sib:

O, Rh positive: Genotype R₀R₂ (cDe/cde)

Blood group of four-year-old sib:

O, Rh positive: Genotype R₁R₀ (CDe/cDe)

Blood group of infant:

O, Rh positive: Genotype R₂R₂ (cDE/cde)

Comments.—In this case, an Rh positive patient of the most common Rh type, Rh₁ (CDe), became sensitized by transfusion or by her first pregnancy or both to the rh" (E) antigen. This patient, even though positive to the Rh₀ (D) and rh' (C) factors, was negative to the rh" (E) factor and became sufficiently sensitized to it to cause severe transfusion reactions and to give birth to an erythroblastotic infant. It is a matter of actual observation that pure anti-rh" (anti-E) is usually produced in Rh positive persons of the genotype R₁R₁ (CDe/cde) or R₁R₁ (Cde/Cde). Persons negative to all three Rh factors who have been exposed to Rh positive blood containing the rh" (E) antigen may also produce anti-rh" (anti-E) but usually do so in combination with saline-agglutinating or incomplete anti-Rh₀ (anti-D).¹³

Case 2.—Sensitization of an Rh Positive Rh₁ (CDe) Patient with Production of Both Anti-rh" (Anti-E) and Anti-hr' (Antic-c)⁷

Clinical Data.—D. B., a white woman, aged 36, had six living children. Her last previous child, born in October, 1953, was jaundiced and spastic. During that pregnancy, that patient had toxemia that was followed by a postpartum nephropathy. In November, 1954, nephrectomy was performed. Two units of blood were administered at that time.

On December 27, 1955, she was referred to the transfusion service of the blood bank in the eighth month of her seventh pregnancy. Crossmatching revealed the presence of a specific anomalous antibody. One 500-cc. unit

of compatible blood (no. R 8174) was given without incident.

In the afternoon of December 27, 1955, after receiving the unit of compatible blood, she experienced false labor and was admitted to the hospital where she received another 400 cc. of group A, Rh positive blood (no. R 8054). The patient experienced chills and fever. There is no record of post-transfusion tests for serum bilirubin or urine hemoglobin. The patient's pretransfusion and post-transfusion blood specimens and the donor's blood causing the reaction were sent to the blood bank for serologic study.

On January 26, 1956, she was delivered of an erythroblastotic, group A, Rh positive male infant. That same day the infant was given an exchange transfusion of A, Rh positive blood, R_1R_1 (CDe/CDe). Rh negative, rr (cde/cde) blood was not selected because it contains hr' (c) to which the mother was sensitized. The infant made an uneventful recovery.

Serological Findings:

Blood group of patient:

A, Rh positive: Genotype R_1R_1 (CDe/CDe)

Blood group of donor No. R 8054:

A, Rh positive: Genotype R_2r (cDE/cde)

Blood group of husband:

A, Rh positive: Genotype R_2r (cDE/cde)

Following the reaction, the patient's serum strongly agglutinated the husband's cells and the cells of the reaction donor (R 8054). The serum contained anti-hr' (anti-c) and anti-rh'' (anti-E). The titer of anti-hr' (anti-c) was 1:1 in saline, 1:8 in 20% albumin and 1:16 by the indirect Coombs test. The anti-rh'' (anti-E) titer was 1:1 by the indirect Coombs test. A month later, immediately following the delivery of the infant, the titer to the hr' (c) was found to be 1:32 in saline, 1:128 in albumin, and 1:128 by the indirect Coombs test. The anti-rh'' (anti-E) titer was 1:1 in saline, 1:2 in albumin, and 1:2 by the indirect Coombs test.

Comments.—Case 2 illustrates dual sensitization in an Rh positive (CDe/CDe) patient. The sensitization was probably initiated by pregnancy and further stimulated by administration of blood. This patient, although Rh positive, became sensitized against two factors in the Rh-Hr system, namely rh'' (E) and hr' (c), both of which she lacked. These factors were present in the blood of the baby afflicted with erythroblastosis and in the blood that produced the hemolytic reaction. It is not rare for persons homozygous to the rh' (C) factor to produce anti-hr' (anti-c) and, if they also lack the rh'' (E) factor, they can produce anti-rh'' (anti-E) as well.¹²

Case 3.—Sensitization in an Rh Positive R_{H_1} (CDe) Patient with Production of Three Antibodies: Anti-rh'' (anti-E), Anti-hr' (Anti-c) and Anti-Kidd (Anti-Jk^a)¹

Clinical Data.—C. S., a white man, aged sixty, group A, Rh positive, was admitted to a Minneapolis hospital on May 17, 1955, for care of a gunshot wound. He was given 4 units of 500 cc. each of homologous blood within twelve hours. Crossmatching difficulties were absent and transfusion reactions were not reported. The patient gave no history of previous transfusions.

Ten days later, additional blood was ordered. Routine crossmatches at the hospital showed incompatibility and the patient's blood sample was sent to the blood bank for crossmatching and further study. Three different antibodies were found in this patient's blood.

Serological Findings:

Blood group of patient:

A, Rh positive: Genotype R_1R_1 (CDe/CDe),

$M,N,S,Le(a-), K-, Fy(a+), Jk(a-)$

The patient's serum contained anti-hr' (anti-c). The titer was 1:2 in saline, 1:16 in albumin and 1:32 by the indirect Coombs test. Anti-rh'' (anti-E) was present in low titer, demonstrable only by the indirect Coombs test in a titer of 1:1. The serum also contained anti-Kidd (anti-Jk^a), active in saline in a titer of 1:4 and in albumin media in a titer of 1:2.

Comments.—This case shows the ease with which certain susceptible persons can become sensitized to numerous antigens even with only one series of transfusions. Not all persons, of course, respond to antigenic stimuli with such alacrity. It is imperative that a record for future reference be kept of the antibodies identified in such a patient because they diminish in time and may not be demonstrable in later routine crossmatching procedures. However, they probably will reappear after the administration of blood containing the offending antigen. The antibody generally takes five to ten days to reappear; after it has done so, it will hemolyze the transfused cells and produce jaundice and a decrease in hemoglobin.

Case 4.—Sensitization of an Rh Positive Rh (CDe) Patient with Production of Three Antibodies: Anti-hr' (Anti-c), Anti-rh'' (Anti-E), and Anti-Duffy (Anti-Fy^a)²

Clinical Data.—L. S., a white man, aged thirty-nine, was group O, Rh positive. On December 8, 1955, the patient, a hemophiliac, was admitted to a Minneapolis hospital with a bleeding ulcer. On December 26, the decision was made to do a subtotal gastric resection.

The patient had been hospitalized many times and had received multiple transfusions of whole blood and plasma. He presented a history of transfusion reactions. Routine crossmatches at the hospital showed the presence of abnormal antibodies. His blood specimen was sent to the blood bank for crossmatching and further study. The three antibodies listed were demonstrated.

During the next six weeks, as large quantities of fresh frozen plasma and numerous units of compatible blood were given, the titer of the Duffy (Fy^a) antibody diminished in strength, possibly because of dilution, and was eventually demonstrable by the indirect Coombs test only. The anti-hr' (anti-c) remained strong.

Serological Findings:

Blood group of patient:

O, Rh positive: Genotype R_1R_1 (CDe/CDe),

$P-, K-, Fy(a-)$

The patient's serum contained anti-hr' (c) in a titer of 1:2 in saline, 1:32 in albumin and 1:64 by the indirect Coombs test. It also contained anti-Duffy (anti-Fy^a) in a titer of 1:2 in saline, 1:1 in albumin and 1:4 by the indirect Coombs test. Anti-rh'' (anti-E) was demonstrable in albumin in a titer of 1:1 and by the indirect Coombs test in a titer of 1:4.

Comments.—This case illustrates the problem of selecting blood for a patient who will require many transfusions over a long period or perhaps throughout life.

It is impractical during the earlier periods of such a regimen to select each blood for transfusion that does not possess some antigens the patient lacks. The development of one or more anomalous antibodies can be anticipated. These antibodies should be identified as they appear and thereafter care must be taken to avoid transfusing the specific antigen. Careful Coombs' crossmatching should be done when subsequent transfusions are given. Furthermore, as in case 3, a record should be kept of the antibodies identified in such a patient to avoid subsequent introduction of homologous antigens in transfusions.

Case 5.—Sensitization of an Rh Positive Rh₁ (CDe) Patient with Production of Anti-P^{5,6}

Clinical Data.—C. D., a white man, aged fifty-six, group B, Rh positive, was admitted on September 8, 1955, to a Minneapolis hospital for diagnostic studies. He gave no history of previous transfusions. He was given two units of blood on September 11 and two more on September 17. No crossmatching difficulties or transfusion reactions were reported. More blood was ordered on September 20. Routine crossmatches at this time with blood available at the hospital showed incompatibility and the patient's blood was sent to the blood bank for crossmatching and further study.

Serological Findings:

Blood group of patient:

B, Rh positive: Genotype R₁r (CDe/cde),
M,N,S,P—,Le(a—),Fy(a+b+),
K—, Jk(a+b+)

Patient's serum contained anti-P, active in saline and albumin in a titer of 1:4 at 37°C, 1:4 at 20°C and 1:16 at 4°C.

The two bloods given on September 17 were rechecked and found to be P negative and compatible with the patient's serum. A specimen from one of the donors whose blood was given on September 11 was found to be P positive. This was the possible sensitizing agent, although no reaction was noted. However, it was thought that this antibody was of the immune acquired variety because:

- 1—It was active at 37°C in albumin as well as in saline.
- 2—It was not detectable in the pretransfusion crossmatching tests at room temperature or 37°C.
- 3—After an interval of two weeks it was not demonstrable at 37°C, but a weakly active anti-P was detected at 4°C.

Comments.—P negative persons frequently have a naturally occurring anti-P agglutinin.³ This is not of clinical significance because it is a cold agglutinin, usually active at 4°C. The fact that this antibody did not interfere with the original crossmatch would seem to indicate that at that time it was either absent or too weak to be detected at 20° or 37°C. This case is unusual in that it appears that a naturally occurring low-titered anti-P may have been enhanced following an antigenic stimulus by a previous transfusion to be-

come an immune anti-P reacting at 37°C. These naturally occurring antibodies may become potentially dangerous in transfusions following stimulation in a P negative patient by previous transfusion or pregnancy.⁴

Case 6.—Sensitization of an Rh Positive Rh₁ (CDe) Patient with Production of Anti-Lewis (Anti-Le^a)^{9,10}

Clinical Data.—E. N., a white woman, aged fifty-five, mother of three children, was admitted to a Minneapolis hospital on October 16, 1953, for treatment of an osteomyelitis of the femur. She had previously received one unit of blood in May, 1952, and two units in July, 1953. No reactions were reported from these transfusions. On October 27, 1953, she received without incident six units of group O, Rh positive blood and on December 10 another unit of O, Rh positive blood. On January 13, 1954, a unit of group O, Rh positive blood was given. Soon after the transfusion was started, the patient complained of pain and a sensation of coldness in the arm. The intern decreased the rate of flow but, assuming that the distress was due to cold blood, permitted the transfusion to continue until a total of 200 cc. had been given, when it became obvious that a true transfusion reaction was occurring. The patient experienced back pain, her temperature rose to 103.6°F. and her pulse rate was increased to 110. Flushing, nausea and vomiting occurred. Six hours after the transfusion, the patient was free of symptoms. Urinary output remained good throughout the subsequent period.

The pretransfusion and post-transfusion blood specimens and a specimen of the donor blood causing the reaction were sent to the laboratory of the War Memorial Blood Bank for investigation.

Laboratory Findings:

January 12: Hemoglobin 10.1 gm. per 100 cc.

January 13: Post-transfusion plasma hemoglobin 490 mg. per 100 cc.

Post-transfusion urine hemoglobin 4 plus (port-wine color) (3 hours after transfusion)

Post-transfusion urine hemoglobin clear (6 hours after transfusion)

January 14: Serum bilirubin 0.73 mg. per 100 cc.

Serological Findings:

Blood group of patient:

O, Rh positive: Genotype R₁r (CDe/cde),
Ms, Ns, P+, Le (a—b—), Fy(a+), K—

Blood group of reaction donor:

O, Rh positive: Genotype R₁r (CDe/cde),
M, N, S, P+, Le(a+b—), Fy(a—), K+

The patient's serum both hemolyzed and agglutinated the donor's cells in saline and albumin crossmatches. Her serum was found to contain anti-Le^a in a titer of 1:8 in saline and albumin media at 25°C, 1:4 at 37°C and 1:4 at 4°C.

Comments.—Case 6 is one in which a Lewis negative (Le (a—b—)) patient experienced a hemolytic transfusion reaction due to Lewis antibodies, apparently stimulated by transfusions of Lewis positive (Le(a+b—)) blood. It does not follow, however, that Lewis antibodies invariably cause reactions. Like anti-P, they appear as naturally occurring antibodies, having low titers. If, however, they have been stimulated to a higher titer by

(Continued on Page 321)

A Survey of Resected and Non-Resected Pulmonary Nodules

O. J. BAGGENSTOSS, M.D.
Minneapolis, Minnesota

THERE has been considerable increased interest in the problem of isolated circumscribed pulmonary lesions with the advent of roentgenographic chest surveys, routine chest roentgenograms on admission to hospitals, pre-employment chest examinations, and advances in thoracic surgery, anesthesia, chemotherapy and antibiotics.

These lesions have been identified by a number of descriptive terms, some of the more common ones being "coin lesions," "isolated pulmonary nodules," "solitary intrapulmonary tumors," "solitary round lesions" and "solitary circumscribed lesions."

It is generally advocated that patients with this type of pulmonary lesion should have the benefit of a thorough history and physical examination. Other diagnostic examinations and tests that may be of positive or negative value are bronchoscopy, with aspiration, cell washings and cultures, sputum examinations, gastric washings and cultures, and skin tests for tuberculosis, histoplasmosis, coccidioidomycosis, echinococcosis and blastomycosis.

Roentgenographic examination of the chest is, of course, the sole means of discovering these nodules; it is also of value in localizing the lesion and in determining the presence of calcification. The question of small flecks or nodules of calcification is frequently equivocal. Calcific densities may lie anterior or posterior to the lesion and vessels seen on end or crossing obliquely may simulate the appearance of calcium. Oblique, lateral and Bucky films may be employed in the further evaluation of these cases. Planigrams are of great help in establishing the presence of calcium and also in proving cavitation. A more recent advantage in the use of planigraphy has been mentioned by Rigler and Heitzman,¹ who described "notching or umbilication" of a nodule that, when definite, is strong evidence of malignancy; however, its absence does not exclude malignancy.

Bronchograms may be of value but are of no aid in the diagnosis when, as frequently happens, these lesions are peripherally located.

Calcification is generally conceded as good evidence of the benign nature of a nodule. In a few rare instances, calcification has been described in circumscribed malignant nodules, and it is conceivable that a malignant tumor could engulf or envelop an area of calcification. Hodes² saw four patients who had calcified primary nodules that ultimately revealed bronchogenic carcinoma. Riemenschneider³ cited one calcified nodule that was pathologically proved to be a tuberculoma with a nodule of bronchogenic carcinoma in its wall. Tuttle⁴ mentioned one resected nodule in which a carcinoma had developed around a previous Ghon tubercle. London and Winter⁵ reported a papillary adenocarcinoma that contained calcium. Tuttle and associates⁶ reported that they have seen three cases of pulmonary carcinoma with x-ray evidence of calcification within the mass, but did not state whether or not these were circumscribed pulmonary nodules.

Nodules with concentric rings of calcification and homogeneously densely calcified nodules are invariably benign. Every effort should be made to locate previous roentgenograms of the chest, if any, as the previous presence or absence of the lesion may well influence the treatment.

Numerous articles have been published, particularly in the past ten years, in regard to the medical, surgical and pathologic aspects of these lesions, along with statistics concerning their malignancy or benignancy. Some authors have established certain criteria for the selection of pulmonary nodules, such as size, usually limited to 4, 5 or 6 cm. in diameter, excluding hilar nodules, calcified nodules, lesions with cavitation, lesions associated with a history of previous malignant disease and those not completely surrounded by pulmonary parenchyma, and lesions with a proved history of pulmonary tuberculosis or with roent-

Presented as an inaugural thesis before the Minneapolis Academy of Medicine, March 19, 1956.

PULMONARY NODULES—BAGGENSTOSS

TABLE I. REPORTED DATA ON RESECTED PULMONARY NODULES

Authors	Total Cases	Malig., Total		Bronch. Ca.		Bron. Aden.	Metast.	Other Malig.	Benign, Total		Inflam.	Ben. Tumor

*Younger age group; 10 patients 20 years of age or less; 6 patients 30 to 39 years of age.

**Bronchial adenomas not listed among the malignant lesions.

***Benign tumors include one diaphragmatic hernia.

†Bronchial adenomas¹² are included among the malignant lesions; calcified lesions are included; 32 lesions contained calcification (25 granulomas and 7 hamartomas); in each of the 17 metastatic lesions, it was known that malignant disease was present elsewhere in the body.

‡Bronchial adenomas included among malignant lesions.

§Found 60 cases among 40,000 films; in 24 cases, the nature of the lesion was not determined.

genographic evidence compatible with pulmonary tuberculosis. Other investigators have set no limitation as to size and include calcified lesions. Variations in statistics could be expected on this basis alone. The majority of published reports have been written by thoracic surgeons relating their personal experience or the experience of the institution with which they were associated. Many of these cases were referred and represented selected cases; these referred cases then undoubtedly underwent further selection by the surgeon. Resected lesions, therefore, although susceptible to definitive diagnosis, do not necessarily reflect the true incidence of malignant tumors among the solitary circumscribed nodules. Occasionally, in reports of resected lesions, mention was made of other pulmonary nodules but no hint was given as to their final outcome. Table I lists some statistics on resected pulmonary nodules.

Present Study

It appeared that it would be of interest to survey routinely discovered nodules, including not only resected lesions but, as far as possible, those that were not resected for various reasons. This study represents a survey of pulmonary nodules encountered at the Minneapolis Public Health Center from 1945 through 1954. Approximately 85,000 persons had roentgenograms of the chest at the Public Health Center during that period.

The criteria for the selection of cases were as follows: (1) Included were any fairly well-defined, single, round or ovoid intrapulmonary lesions. Lesions that appeared to touch a pleural surface were not excluded, as these may well grow out to the periphery of the lung and in the last analy-

sis offer the same problem as if a small amount of lung tissue was interposed between them and the pleura. (2) Nodules in the hilar region were excluded. (3) Cases were excluded if there was evidence of cavitation or calcification in the nodule on postero-anterior, lateral, oblique or Bucky roentgenograms. Cavitation is usually regarded as an indication for removal. (4) The lesions were not more than 4 cm. in diameter. (5) No cases were included in which a history of proved pulmonary tuberculosis or definite roentgenographic findings of tuberculosis or both were present. Cases in which a small calcified Ghon complex or small calcifications in the hilar regions or a fibroid deposit or two in the apices were present were not precluded, as such lesions are extremely common and I do not believe any surgeon would hesitate to operate because of their presence. (6) No cases in which known malignant disease was present elsewhere in the body were included, as this lends an entirely different aspect to the problem.

Records of 104 isolated nodules that fulfilled the above criteria were found in the period from 1945 through 1954. As was expected, difficulty was encountered in following these patients, as a number represent transients and many have a shifting address within the city, frequently not being co-operative regarding follow-up studies.

A total of twenty-four lesions were resected (Table II). Three of these lesions were carcinomas and one was a bronchial adenoma, giving an incidence of malignancy of 13 or 17 per cent, depending on whether or not bronchial adenomas are considered malignant.

Eighty lesions in this series were not resected

PULMONARY NODULES—BAGGENSTOSS

TABLE II. CLASSIFICATION OF TWENTY-FOUR RESECTED LESIONS

Malignant	Questionably Malignant	Benign 20	
		Tumor 2	Inflammatory 18
Carcinoma 3	Bronchial adenoma 1	Hamartoma 2	Tuberculoma 8
			Granuloma 6
			Histoplasmosis 2
			Organized infarct or unusual granuloma 1
			Coccidioidomycotic granuloma 1

TABLE IV. AGES OF 104 PATIENTS SURVEYED

Age, Years	Patients

50-59	23
60-69	20
70-79	5
80 or more	2
Total	104

(Table III). Of these cases, thirty-four were followed less than one year and ten from one to two years, producing a total of forty-four followed less than two years. This is too short a time to allow any assumption concerning their nature, except for one lesion that was observed from one to two years and proved to be metastasis from a renal carcinoma. Another case followed from one to two years finally was diagnosed as a bronchogenic carcinoma of the left lower lobe from roentgenographic and clinical studies. The nodule of interest in the present study was in the right upper lobe, and it is impossible at this time to determine whether or not any relationship existed between these two lesions. There was a probable slight increase in size of one lesion in the group followed from one to two years. However, this does not necessarily denote malignancy, as benign tumors and inflammatory masses may increase in size.

Thirty-six patients were observed for two or more years and twenty-three patients were followed for four or more years. If it is assumed that these twenty-three lesions were benign because of the four years or more of observation and if they are added to the resected nodules, the incidence of malignant lesions is approximately 6 or 9 per cent, depending on whether or not bronchial adenomas are considered malignant. It is, of course, rare for a malignant lesion of the lung to remain static for two or more years and rare indeed for one to remain static for four or

more years, particularly without the use of chemicals, hormones or radiation therapy. I have heard of one solitary circumscribed pulmonary nodule that was present for seven and one-half years and then a carcinoma was found at the site during operation.¹⁵ Whether this was a carcinoma from its inception or whether a carcinoma developed near a benign lesion is pure conjecture.

From Table IV it may be noted that the majority of these patients fall into the fifth, sixth and seventh decades of life, not a particularly young age group.

A review or recommendation by the Committee on Suspected Chest Abnormalities of the Hennepin County Medical Society was noted on seventy-four charts of this series. These are summarized in Table V.

It would appear that the percentage of malignant lesions in unselected circumscribed pulmonary nodules is appreciably lower than in a selected series of surgically treated lesions, of which many are doubly selected, first by the referring physician and then further by the thoracic surgeon. This selection is undoubtedly made on the basis of history, age of the patient, appearance and size of the lesion, availability of previous roentgenograms showing the presence or absence of the lesion,

demonstration of calcification within the nodule and the weighing of the positive or negative findings in skin tests, smears, cultures and other examinations. Such study and selection are of particular importance in the poor-risk patient, for whom the hazards of surgery must be seriously weighed against the implications of the lesion.

This report should not be interpreted as an attempt to minimize the seriousness of the problem of the pulmonary nodule or to encourage an attitude of watchful waiting. All of these patients deserve the advice and consultation of one thoroughly familiar with the problem.

Benign tumors, it is generally acknowledged, are best treated in many instances by resection and this is also true in some cases of inflammatory nodules. Benignancy of a certain number of pulmonary nodules can be well established without surgical intervention but in the majority of isolated pulmonary nodules the problem cannot be resolved except by resection, followed by microscopic examination of the specimen and cultures in some cases of inflammatory lesions.

TESTS ON EFFECT OF TRANQUILIZERS ON HUMAN BEHAVIOR, DRIVING ABILITY

A battery of testing devices, designed to show how drugs like the tranquilizers affect normal human behavior and skills—such as those required for safe driving—was demonstrated at a meeting of the Michigan Clinical Institute held at the Sheraton-Cadillac in March. The tests were developed for use by the Mental Health Research Institute of the Department of Psychiatry, University of Michigan.

Dr. James G. Miller, Professor of Psychiatry at the University, who described the apparatus, said such devices have been used at the Mental Health Research Institute to determine what effect, if any, "Miltown," one of the tranquilizing drugs, has on the skills required for safe driving.

These studies, conducted by Dr. Miller and Drs. D. G. Marquis, E. L. Kelly, R. W. Gerard and Anatol Rapoport, showed that even when given in twice the ordinary single dosage, "Miltown" had no effect on driving ability, as measured by driving, steadiness and vision tests.

In the "Miltown" study, fifty normal subjects were given twice the regular dosage of the tranquilizer and, after the drug took effect, were asked to take a special driving test. The object of the test is to use ordinary

automobile controls to steer a model car which rests on a belt. Accuracy of steering at various speeds is measured, and the reaction time—the time it takes to hit the brakes when a red light appears—are also measured.

To eliminate any chance of misinterpretation in the "Miltown" study, each subject was given five different "drugs" over a five-day period and was tested each day for the effect of the particular drug on his behavior. The drugs included, in addition to "Miltown," a "dummy" drug, a "dummv" plus a shot of whiskey (one ounce of 86 proof), "Miltown" plus the whiskey, and "Dexedrine."

The tests also corroborated the well-known fact that alcohol "significantly worsened performance," Dr. Miller said. Subjects given alcohol plus "Miltown," however, were no worse than when given alcohol alone.

Pointing to the wide use of tranquilizers, and to the need for more information concerning their influence on the senses, Dr. Miller explained, "We hope with sensitive and precise tests of this sort to be able to get effective evaluation of behavioral toxicity of these drugs."

A Fatal Granulomatosis of Childhood

The Clinical Study of a New Syndrome

HEINZ BERENDES, M.D.,
ROBERT A. BRIDGES, M.D.,
ROBERT A. GOOD, M.D.
Minneapolis, Minnesota

IN 1950 a twelve-month-old-child was referred to the University of Minnesota Hospitals with a syndrome consisting of chronic, suppurative lymphadenitis, pulmonary infiltrations, hepatosplenomegaly and an eczematoid dermatitis about the eyes, nose and mouth. Since then we have seen three other children with an almost identical syndrome. We believe that this is a distinct entity not previously described in the medical literature. This syndrome, as we have observed it, follows a malignant course and at this time has been responsible for the death of three of our four patients. Of the many approaches we have taken in the management of these patients, none have proven successful and the disease has relentlessly progressed through severe debilitation to ultimate death of the patient.

Clinical Manifestations

Chronic, suppurative lymphadenitis was the presenting complaint in all of these children. Cervical lymphadenitis was present in all four patients, but involved the axillary area in two patients, the inguinal area in two patients and the epitrochlear area in another child. In three out of the four children this process started during the first year of life. One child developed his first symptoms at two years of age. Hepatomegaly was observed in all four children, while splenomegaly was present in three. Though the degree of splenic enlargement varied during the course of the disease, it did not seem to be correlated with the clinical severity at any particular

time. All of these children suffered an eczematoid dermatitis involving the eyelids and periorbital skin. The skin about the mouth and external nares was commonly involved in the same process. A serosanguinous nasal discharge was present at times. Over the face this dermatitis was associated with a chronic blepharoconjunctivitis that has been present in all of our patients. In one child the cornea became involved and resulted in considerable residual scarring. Three out of the four patients developed pulmonary infiltrations during the course of the disease. These infiltrations were present in a variety of pulmonary segments. At times clearing of this process was evident, but with continued observation these areas of consolidation recurred either in the same segment or in a previously uninvolved area. Pleural effusions were present in two of these patients.

It should be noted that during the first year of illness the chronic lymphadenitis was the most prominent clinical manifestation. This process seems gradually to abate while the pulmonary disease and general debilitation dominate the clinical picture during the latter stages of the disease. Death has occurred in three patients after an illness of two to three-and-a-half years. Our remaining child has had his disease for a little over one year.

All of our patients were boys. In one child there was a most provoking family history. In three previous generations on the maternal side of this boy's family, with the exception of the grandfather and great-grandfather, all the male members died during infancy with a syndrome described either as boils and septicemia or scrofula. The maternal grandfather had a similar process involving the left cervical area during infancy. He survived, however, though at this time, according to the patient's mother, he still has a mass present in the cervical area.

Fever was invariably present during the major

Dr. Good is American Legion Memorial Heart Research Professor of Pediatrics.

portion of the disease. This did, however, vary greatly in severity. During the course of the disease there were periods of temporary improvement lasting up to several months. Marked growth failure became manifest shortly after the onset of the disease and continued throughout the remainder of the illness.

Laboratory Findings

No specific hematologic abnormalities were noted, though all of the patients exhibited varying degrees of anemia and polymorphonuclear leukocytosis. Brief intervals of eosinophilia were seen in two children and, in one, reached a peak of 20 per cent. There was no evidence of renal disease. Marked hypergammaglobulinemia was found in all four children. The gamma globulin levels ranged between 2 and 5 gm/100 ml., although there was considerable variation within this range in the individual patient. The degree of hypergammaglobulinemia was not correlated with the severity of the disease at any particular time. A striking elevation of the α -2 globulin was also seen on the electrophoretic pattern. No abnormalities of liver function were present except for an elevation of the zinc turbidity consistent with the known levels of gamma globulin.

Because of the striking resemblance to an infectious process, we have used every available means for the isolation of a pathogenic agent. Materials for cultural examination have included blood, urine, aspirated bone marrow, spinal fluid, pus from draining lymph nodes, aspirated material from suppurating lymph nodes, granulomatous nodes obtained by biopsy, and liver biopsy specimens in two patients. A granulomatous segment of lung was obtained from one of our patients. Appropriate media was used for isolation of a variety of pathogens, including the brucella species, *mycobacterium tuberculosis*, *pasteurella tularensis*, nocardia, *blastomyces dermatitidis*, and other pathogenic fungi. In two of the four patients lymph node homogenates were inoculated onto the cornea and into the anterior chamber of the eye in rabbits and intraperitoneally in mice, rabbits, and guinea pigs, and onto the chorio-allantoic membrane of the chick embryo. In addition, we have used a variety of tissue culture strains in an attempt to isolate a cytopathogenic agent. These tissue strains included one which was started from an explant of liver tissue obtained from one of our patients. In all of these

attempts we have failed to isolate an agent to which we could attribute the various manifestations of the disease. At times staphylococci have been demonstrated in suppurating lymph nodes. Because of the absence of staphylococci in the granulomatous nodes obtained at biopsy, we feel that this represents secondary infection of an open suppurating wound. Various serologic procedures were used in an attempt to demonstrate antibodies against brucella, *pasteurella tularensis*, and salmonella. Skin testing was performed with a variety of antigens including tuberculin, histoplasmin, blastomycin, coccidioidin and a cat scratch preparation. These tests were negative, with the exception of one child whose Mantoux apparently became positive in the course of his disease. Frei antigens injected intradermally in two patients gave negative results. Kveim antigen did not reveal any sensitivity in two of our patients.

Pathology

Gross examination of the areas of suppurative adenitis showed pockets of purulent material and a network of sinus tracts. Microscopic examination of involved lymph nodes revealed areas of central necrosis surrounded by mononuclear cell infiltration, together with multinucleated giant cells. There were striking numbers of both mature and immature plasma cells in these areas. Pulmonary granulomas of a similar nature were found in the biopsy material obtained at the time of an exploratory thoracotomy in one of our patients. Similar lesions were seen in two other patients on examination of postmortem material from their lungs. Liver biopsies obtained from two patients revealed the presence of multiple small granulomas of similar structure to those previously described. Bone marrow aspiration showed an increase in plasma cells. Postmortem examinations in the three children who have expired with this disease have failed to reveal further information as to the nature of the disease process. Extensive studies of biopsy material and postmortem material with Gram stain, acid fast, periodic acid Schiff and routine stains have not revealed evidence of an underlying etiologic agent. Two of these deaths were the result of staphylococcal empyema that developed in the last weeks of their illness and terminated with staphylococcal septicemia.

Attempted Therapy

Our management of these patients was largely empirical since the etiologic nature of the syndrome remains unexplained. We have attempted therapy with various antibiotics for long periods of time. Chloromycetin and erythromycin were used in high doses for periods of at least one month. Combinations of penicillin and sulfadiazine and the various tetracyclines have been used in all of our patients for periods of one to several months. Novobiocin has also been tried without effect. Two of our patients were treated for periods of six weeks to six months with PAS, streptomycin, and isoniazid. In none of the patients did any of these measures produce a demonstrable effect on the course of the disease. We have administered large amounts of gamma globulin to three of our patients. Alternating small blood and plasma transfusions were used for periods of six weeks in one of these children. Local x-irradiation was administered to the cervical area of two children. None of these therapeutic efforts appeared to alter the course of the disease process at any time.

Discussion

The picture presented by these children demands the consideration of an infectious agent as the prime plausible etiologic factor responsible for this disease. Clinically, these children have a syndrome indistinguishable from the descriptions of scrofula that appear in the older literature. We have made exhaustive attempts to isolate some agent which might be responsible for this disease. The only positive cultures that we have been able to obtain were those from areas which were potentially open to secondary infection. From these areas we have, on a number of occasions, cultured coagulase positive staphylococci. These were obtained from areas where there was a co-existent draining adenitis. We have, however, on an equal number of occasions, been unable to recover staphylococci from similar areas. It appears that in the development of the granulomatous adenitis there is an early phase in which these nodes are always sterile and a later phase in which the granulomatous area becomes necrotic, suppurates and may drain spontaneously. It is in this later phase that the staphylococci may gain entrance to these diseased tissues. The pathologic lesions of the lymph nodes in cat scratch disease are indis-

tinguishable from those seen in our patients.¹ However, neither the course of the disease nor the distribution of the lesions we have described can be considered to bear more than a superficial resemblance to cat scratch disease. Skin tests with potent cat scratch antigen were applied in three of our four patients and were negative. Further, none of these children had sustained cat scratch or cat bite prior to the development of his disease.

These investigations have led us to conclude that if there is some agent responsible for this disease it is such that it escapes detection by the currently available techniques. In the light of this vast array of negative information it seems to us more likely that this syndrome which we have described is more closely related to such conditions as Hodgkin's disease and the reticuloendotheliosis. It should be remembered that these diseases have been considered by many in the past to represent some bizarre response on the part of the host to an infectious agent.² The innumerable attempts to obtain direct proof for this assumption have been as fruitless as our own attempts with this new syndrome. On consideration of the clinical and pathologic aspects of those diseases that lie on the ill-defined borderline between infection and malignancy, there is evident a striking resemblance both with each other and with the new syndrome we have described in this paper. Such syndromes, however, may be distinguished from one another on the basis of their clinical and pathologic aspects. Such differences have provided the logical basis for considering them as separate disease entities although their basic etiologic nature remains obscure. Of the various granulomatous diseases that are distinct entities, sarcoidosis is probably the most difficult to separate conclusively from this new syndrome.³ The syndrome of sarcoidosis, as described in the adult, is one of a benign involvement of a variety of tissues in a granulomatous process. These lesions, when they occur in various groups of nodes, are generally firm and virtually never become necrotic or drain spontaneously through the skin as in tuberculous adenitis. A variety of osseous and cutaneous lesions have been described in association with sarcoidosis. No lesions of this character have been noted in the children described in this report. Neither were the pulmonary lesions that we have observed those of sarcoid. In spite of such great difference in the character of these two syndromes, and its extreme

rarity in childhood, it still remains a remote possibility that this malignant granulomatous disease is actually a childhood expression of sarcoidosis. There are two other syndromes of granulomatous disease that bear a somewhat closer resemblance. These are Wegener's⁴ granuloma and the midline granuloma⁵⁻¹¹ of the face. Wegener's granuloma is a generalized disorder in which there is a granulomatous destruction involving first some portion of either the upper or lower respiratory tract. At the periphery of these lesions there is always an arteritis indistinguishable from that seen in periarteritis nodosa. At some stage of this disease there is always evidence of renal involvement. Such characteristic lesions were not present in our patients. Midline granuloma of the face is a somewhat similar destructive process involving the mucosa of the upper respiratory tract, which progresses by direct extension to eventually destroy an extensive area over the face. The locally destructive nature and the limited area of involvement serve to distinguish this disorder from the syndrome that we have described. There are other disorders in which there is a granulomatous response on the part of the host. Certain irritants being introduced into various areas result in granuloma formation as has been shown for the so-called pyogenic granuloma and the pulmonary and cutaneous granuloma that have resulted from beryllium.¹² In these children no evidence was present to suggest exposure to such an agent nor was the distribution of the lesions of a similar nature. In 1954, Janeway and Craig¹³ described a group of five children with hypergammaglobulinemia, leukopenia, and increased susceptibility to staphylococcal and pseudomonas infections of the skin and respiratory tract. In none of these cases, however, were granuloma seen, and the two conditions, although superficially similar, must be considered to be separate entities.

Our studies of this disease have left us with the feeling that it may represent a generalized disorder of the reticuloendothelial system. If the various collagen diseases can be considered as peculiar sensitivity reactions, whose manifestations depend upon the particular tissues subject to this sensitivity reaction, then it is certainly plausible in this malignant granulomatous disease that we have described that the reticuloendothelial system might be the shock organ whose fundamental alteration

and eventual destruction results in the clinical picture presented.

Summary

1. Four male children suffering from a previously unreported syndrome consisting of chronic suppurative lymphadenitis, hepatosplenomegaly, pulmonary infiltrations and eczemoid dermatitis of characteristic distribution have been described. These manifestations are the result of a generalized granulomatous process and are associated with a striking hypergammaglobulinemia.

2. This new syndrome has been differentiated from recognized forms of infectious and noninfectious diseases producing granulomatous processes in childhood.

3. Extensive empirical efforts at treatment of the disease have been without effect upon the relentless progression that would seem to be a most characteristic feature of this syndrome.

Carcinoma of the Rectum and Sigmoid Colon

CHARLES A. NEUMEISTER, M.D.
Minneapolis, Minnesota

IT IS NOT the intention of this paper to cover the broad subject of carcinoma of the sigmoid and rectum completely but, rather, to attempt to stimulate our thinking on this disease and to re-evaluate the various methods of treatment which have been evolved for this particular malady.

In the past few years there has been a general trend toward extending the scope of operations and removing more and more tissue in the hope that a greater number of cures could be obtained. We have, I believe, arrived at a point now where, if we are going to extend further our operations for this particular affliction, we are probably going to have to do something of the magnitude of amputation at the waist. Operations which have been done by Brunschweig and his group eliminate from the pelvis all of the structures which can be sacrificed without sacrificing the bony pelvis and its associated structures. It will be interesting to see what the long term survivals are going to be on a procedure of this type. However, from the early published figures, it begins to look as though the survival rates will not be significantly higher than the survivals from the conventional type operations. In a recent report, Brunschweig et al quoted an operative mortality of approximately 20 per cent, which is about three or four times the accepted mortality for the conventional operations for cancer of this region. One wonders whether the greater salvage rate of such extensive surgery would be justified in view of this rather high surgical mortality rate.

In view of evidence that has been presented regarding the behavior of cancer both before and during operations, I believe that it is far more important for the practicing surgeon, who is called upon to treat carcinoma of the rectum and sigmoid, to pay greater attention to surgical technique in doing the surgery which is required to remove the lesion and the adjacent lymph nodes,

rather than to make an attempt to extend the operation and do what I think is still more or less an experimental procedure. Fisher and Turnbull at the Cleveland Clinic made a very excellent study of the spread of cancer by examining venous blood which is removed from the veins of the resected specimens, in carcinoma of the sigmoid and rectum, and found that in 32 per cent of cases there were carcinoma cells in the venous blood which had been trapped in the veins at the time of operation. This study was repeated by Adamson at the Lahey Clinic and the results were duplicated exactly. On the basis of this, it is certainly quite evident that extension of the operation to include another inch or inch and a half of lymph node tissue is going to do very little about the carcinoma cells which have been squeezed into the veins, have gotten into the portal circulation and perhaps are lodged in the liver at the time of the surgery. On the basis of this, ligating all of the blood supply before any manipulation of the tumor may conceivably help us to prevent some of the hematogenous metastases which have been the cause of death in by far the greatest percentage of our patients, and I am sure that this has been the experience of most of the people who are doing this type of surgery. Dukes published a very excellent review of the resected specimens at St. Mark's Hospital and found that 17 per cent of all resected tumors already had blood vessel invasion at the time of resection. The Lahey Clinic group in reviewing a series of 900 cases of carcinoma of the colon and rectum found that 28 per cent had blood vessel invasion at the time of resection. Grinnell published a series of cases which also revealed a 36 per cent incidence of blood vessel invasion in the resected specimen.

It should go without saying, in face of these figures, that even a minimal amount of manipulation of the tumor prior to ligation of the blood supply certainly will serve to enhance further spread of the disease which may have already spread at the time of the operation.

A word about isolation of the tumor within the lumen of the bowel by placing a tie around

Dr. Neumeister is Clinical Instructor in Proctology, Department of Surgery, University of Minnesota.
Presented at the Minneapolis Surgical Society, November 1, 1956.

the bowel proximal and distal to the tumor, as advocated by Cole and his group. As a principle, I think this is an excellent one, inasmuch as manipulation of the tumor is certainly likely to break off either gross pieces of tumor or rub off cancer cells into the lumen of the bowel and cause a greater contamination of the anastomotic line. However, this procedure perhaps is of less importance than the very early ligation of the blood supply, inasmuch as this tumor has been shedding cells during its natural life prior to the time of surgery and there doesn't seem to be any good way of eliminating these cells from the lumen of the bowel by the use of any cauterizing agents or any other chemical means. It is, however, an added precaution that one should and can take without increasing the operative risk and may serve to prevent some recurrences or implants at the line of anastomosis. In our experience over the past five years we have not had occasion to see a patient who had a recurrence in the line of anastomosis. However, we still feel that the added safety factor of this rather simple procedure is well worth while.

The question, at what level should one do an abdominal-perineal resection and at what level should an anterior resection with end-to-end anastomosis be the procedure of choice, is one which at the present time is still open for discussion. As you all know, Bacon and his group at Temple University have been championing the abdominal-perineal pull-through operation for nearly all lesions other than those that are within the lower 5 or 6 cm. of the bowel. In conversations with this author it was my understanding that at the present time they are not doing this operation for any lesion below 12 cm. but are doing the abdominal-perineal resection with permanent colostomy. In the July issue of *Surgery, Gynecology and Obstetrics*, there is a very excellent article and analysis of "Carcinoma of the Rectum and Rectosigmoid" by Mayo and Fly from the Mayo Clinic. Their conclusion was that a lesion above the 6 cm. level to the 15 cm. level could be treated with anterior resection and end-to-end anastomosis with a five-year survival which was comparable, statistically, with the abdominal-perineal resection. Comparative figures being 50.8 per cent for anterior resection with end-to-end anastomosis and 54.8 per cent after combined abdominal-perineal resections. This is in a sta-

tistically significant series of cases. Waugh and his group published a series of cases of five-year survival after the abdominal-perineal resection with the pull-through sphincter preserving operation and had a five-year survival of 51.5 per cent. On the basis of studies of this sort it would seem that it would be necessary for us to keep an open mind on whether lesions should be categorized as to level from the anal sphincter as to whether or not the more mutilating procedure of abdominal-perineal resection should be carried out. I am thoroughly convinced that there are certain rather large lesions which occur at the 8 to 10 cm. level in which the prognosis might be better with the more radical procedure with permanent colostomy, whereas there are smaller lesions at a lower level that might be adequately treated by anterior resection.

In our present state of knowledge I don't believe we can categorically lay down any hard and fast rules as to the treatment of carcinoma at any particular level in the rectum and rectosigmoid. This, of course, brings up the question whether there are any carcinomas which should be treated by simple local excision without removal of all of the adjacent lymph node bearing tissue. There certainly must be a time when a carcinoma is localized without any spread to any adjacent tissues or to the adjacent lymph nodes and, with teaching being that the more radical operation should always be done for the smaller lesion, one cannot help but wonder whether rectums and sphincters are not being sacrificed needlessly in early cancers.

We have had occasion in the past four years to follow two patients who had as nearly identical lesions as it is possible to get. Both of these patients were in their middle fifties. At the time they were first seen both had a small carcinoma of the rectum on the posterior wall at 4 cm. from the anal verge. Each lesion measured approximately 1.5 cm. in diameter. Both of them were somewhat questionable, grossly. Both were treated by excision biopsy. On both resected specimens of the biopsy specimen, the pathologic report was that of invasive carcinoma. Both patients were advised to have abdominal-perineal resection. One patient agreed to this procedure and was subjected to it. The other one flatly refused to have a colostomy and chose to take her chances on recurrence and later abdominal-perineal resec-

tion if there was any recurrence. Up to this date both have been checked and followed at intervals of six months. I have seen both of these patients in the past thirty days. Neither one has any evidence of recurrences nor any evidence of distant metastases. It would seem that the patient with the more conservative operation has in this instance as good a chance of cure as the patient who was subjected to a considerably greater operation with a greater risk and resultant handicap in the form of an abdominal colostomy.

I was able to find in our files four other patients who had had small carcinomas in the rectal ampulla who also refused a more radical operation and who were treated by local excision of their tumor, and they have all had an excellent result. More than three years has elapsed since these four patients underwent surgery.

Within the past six weeks we had occasion to treat a patient who had a small sessile polypoid lesion at the 22 cm level. This lesion measured approximately 6 mm. in diameter. It was removed with a biopsy forceps and the base was thoroughly fulgurated. This was a patient in her middle forties and the pathologic examination revealed this lesion to be a Grade III carcinoma. The patient was advised to have segmental resection with end-to-end anastomosis. The entire sigmoid colon, lymph nodes and the entire mesentery up to the origin of the inferior mesenteric artery was removed with the resected specimen and an end-to-end anastomosis done. Serial sections through the base of the lesion failed to reveal any evidence of any tumor cells left and the lymph nodes were negative. One cannot help but wonder if in a patient of this type the fulguration and local removal were not adequate treatment.

In summary I should like to point out, first, that it seems greater attention to minor details of surgical technique could very well be responsible for improving our survival rates from carcinoma of the rectum and rectosigmoid as well as the rest of the colon.

Early and localized cancer of the lip has a good chance of permanent cure by irradiation. Surgery may be necessary for resistant, recurrent or late radiation ulcers.

* * *

It is inadvisable to attempt to treat a person for malignancy and pretend it is benign.

MAY, 1957

Second, I should like to re-emphasize that there is considerable question whether or not extensive and radical operations will significantly lower our mortality rate for carcinoma of these organs, particularly when one considers the greater mortality rate which is associated with these extremely radical, mutilating operations.

Third, in the treatment of low-lying lesions between the 6 and 15 cm. level of the rectum, the question of whether to do an anterior resection with end-to-end anastomosis or whether to do an abdominal-perineal resection with permanent colostomy is, I think, still far from settled, and at the moment it would seem that the better approach would be to individualize the lesions. The results which will be obtained by these two operations will perhaps be greatly dependent upon the operator's judgment of and previous experience with treatment of this disease.

Fourth, there are some lesions which certainly are amenable to treatment by local excision and our main problem seems to be to determine which ones can be treated in this manner and which ones would require more extensive operations.

Last, I believe the proper operation for any given carcinoma of the rectum or colon is that operation which will be radical enough to give that particular patient the best chance of a permanent cure with the lowest possible mortality rate in any given case. It is my feeling that we cannot categorize in the treatment of this disease, that each patient represents an individual case that must be evaluated on the basis of the findings and the patient's general condition, and the proper operation should be performed which will give that patient the best chance of being permanently cured.

I still believe in radical surgery for carcinoma and present these arguments as a stimulus to myself and to others to keep an open mind on a question which I feel is still not settled. We will see further changes in therapy of this disease and I am sure that the ultimate answer will lie in something other than surgery.

Doubt and fear may be more devastating than a knowledge of the true facts, even though the true facts in the case of incurable malignancy are certainly not the best.

A cancer patient who wishes to know what his condition is, is often actually relieved to know the bitter truth.

Poison Control Center—A Community Need

ALBERT J. SCHROEDER, M.D.
Minneapolis, Minnesota

ACCIDENTAL poisoning has become one of childhood's most common nonsurgical emergencies. This fact needs little emphasis for the pediatrician and practitioner who is all too frequently beset by the emergency calls concerning children who accidentally ingest poisonous substances. Physician awareness of the problem is now generally achieved, but less impressive progress has been made in prevention and treatment. Approximately 14,000 accidental deaths per year occur among children one to fourteen years of age in the United States. In 1954, there were approximately 1,400 fatal home poisonings.¹ As significant as these numbers may be, they fail to convey the staggering morbidity of nonfatal poisonings which outnumber the fatalities many hundreds to one.

Advances in chemistry, manufacturing processes and distribution have put tremendous numbers of potential toxic substances in nearly every modern household, and especially on the farm. The Committee on Toxicology of the American Medical Association estimates that over 250,000 trade name substances are currently on the market. The physician is frequently frustrated in an effort to determine from the information on hand the toxic ingredient of many common household agents. The problem is further compounded because the formulas of many of these substances are trade secrets and from time to time their ingredients may be changed and altered without changing the original name of the product.

Thus has come a need of physicians from all parts of the country for up to date information on toxic ingredients in common substances found in modern homes and farms. This has been an important stimulus for the formation of poison control centers.

In 1950, the American Academy of Pediatrics recognized the importance of the acute poisoning problem in children by authorizing and appointing a committee on Accident Prevention. Through

the stimulus of the Academy and its Accident Prevention Committee, there are now functioning eighteen poison control centers in cities of the United States.² Such centers collect and process data on the incidence and type of poisons encountered. Such local control centers, cooperating with the other state and national centers could provide prompt information on toxic ingredients and the treatment for a particular agent in the bewildering array of poisonous substances ingested by children. As a result of information already gained through these functioning centers, a most useful reference guide to the chemical constituents of common household substances together with treatment recommendations has been published.³

Total	868						

Data

A summary of data on accidental poison ingestion in children under fifteen years over a five-year period, as recorded in the emergency room of Northwestern Hospital, Minneapolis, Minnesota, is presented. The total number of cases reviewed was 868. (Table I) When one realizes this general hospital is one of thirteen serving the metropolitan area of Minneapolis, the total morbidity for the area, if calculable, would be impressive.

As is well appreciated, the curiosity of the toddler results in children in the age group of eighteen months through two years encountering poisons most frequently (Table II). Boys in each

Read at the fall meeting of the Northwestern Pediatric Society, Bayport, Minnesota, September 28, 1956.

age group and in the total series outnumber girls.

An analysis of cases by groups is presented in Table III. Medicines, (group 1) conventionally considered under household substances, have been considered separate to emphasize their importance. If all medicines could be kept in the medicine chest and the medicine chest locked, the major source of poisons in this series could be eliminated.

Under household substances (group 2) are included cosmetics, toilet goods, cleansing, polishing, and sanitizing agents, disinfectants, fuels et cetera. The variety of these products runs into the thousands.

Pesticides (group 3) consist of a large group of chemicals for use as insecticides, herbicides, fungicides, rodenticides, and insect repellents. These are generally highly dangerous poisons.

The most common types of poisons encountered in this series are found in Table IV. Largely responsible for the prominence of aspirin as a poison is its popularity and wide distribution in special flavored forms. As all who deal with this problem are well aware, "candy aspirin" presents our most frequently encountered drug. (Table V) Since 1932, candy aspirin has been sold as a prescription drug, but only since 1948 has the flavored form of children's aspirin had been distributed as an over-the-counter remedy. This type of aspirin is sold largely through drugstores where it now constitutes approximately 12 per cent of the total aspirin sales.⁴

Of the 868 cases of ingestion poisonings encountered, forty-one or 5 per cent required admission and treatment in the hospital. (Table VI) There was one fatality, this due to ingestion of Digitoxin by a two-year-old girl.

In the State of Minnesota during the five-year period of this study (1951-1955), there were thirty-nine deaths due to poisonings by ingestion in children under fifteen years, and all but one were under the age of five years.⁵ The state morbidity figures for accidental poison ingestion in childhood, judged by the numbers encountered in one metropolitan hospital emergency room, must indeed be impressive.

Summary

1. The data on cases of accidental poison ingestion in children encountered in a metropolitan hospital emergency room are presented. These results are summarized in tabular form.

2. A wealth of information and experience in accidental poisoning in children passes through our hospital emergency rooms yearly. This information, now largely lost, could be processed and correlated through the function of a poison control center. Such a center would contribute to *education* in the subject, stimulate means of *prevention*, and improve *treatment*.

Effect of Bilateral Adrenalectomy on Diabetes Mellitus

HERMAN J. WOLFF, M.D., PH.D.
B. J. KENNEDY, M.D.
Minneapolis, Minnesota

MORRIS B. JOHNSON, M.D.
Saint Paul, Minnesota

THE RELENTLESSLY progressive vascular disease seen in some patients with diabetes mellitus is a grave yet stimulating medical problem. Juvenile diabetic patients are especially prone to have premature arteriolar degeneration, with vascular lesions making their first appearance from five to fifteen years after the onset of clinical diabetes.¹

Microaneurysms in the retinal arterioles are often easily recognized in the early stages of vascular degeneration and the kidney frequently follows as a major clinical area of impact.² Kimmelstiel and Wilson³⁻⁵ described a clinical syndrome in diabetic persons associated with intercapillary glomerulosclerosis characterized in the advanced stages by hypertension, retinitis, nitrogen retention, proteinuria and hypercholesterolemia, with eventual renal failure and death.

The exact etiologic stimulus for the production of these vascular changes has not been found, but it appears possible that such vascular degeneration represents a disease of adaptation.⁶⁻⁸

McCullagh and Alivisatos⁹ pointed out that diabetes mellitus must be looked upon as a group of diseases that have hyperglycemia as a common feature. Long-sustained hyperglycemia, whatever its cause, may in some persons precipitate lasting pancreatic diabetes. In addition, hyperglycemia is a fairly potent stress factor capable of increasing the susceptibility of diabetes to the so-called adaptation response.¹⁰ Insulin hypoglycemia is likewise a stress factor in that insulin shock is a

potent stimulant of adrenal cortical dysfunction.¹¹

Kinsell and his group¹² considered clinical diabetes to be the relative or absolute lack of the hypoglycemic factor and the relative or absolute excess of pituitary, adrenal and possibly other hyperglycemic factors. They suggested that a major factor in the vascular degeneration in persons with diabetes may be the constant disturbance of intracellular and extracellular osmotic relationships resulting from extreme fluctuation in blood sugar over months and years.

In 1953, Poulsen¹³ reported the disappearance of diabetic retinal lesions in a female with longstanding diabetes following the onset of Sheehan's syndrome. He suggested, as did Kinsell and co-workers and McCullagh and Alivisatos, that diabetic retinopathy is the manifestation of a metabolic hormonal disorder characterized not only by lack of insulin but also by the unrestrained action of the pituitary and adrenal hormones. Similarly, Becker¹⁴ showed that retinal microaneurysms can be produced by the injection of corticotropin into rabbits rendered diabetic by alloxan. Vascular lesions associated with Cushing's syndrome likewise suggest that excessive adrenal cortical steroids have a direct etiologic relation to the vascular damage. However, it has not been shown that the so-called steroid diabetes of Cushing's syndrome causes diabetic retinopathy more frequently than does clinical diabetes mellitus.

Hypoglycemic and hyperglycemic stress factors and resultant adrenal cortical dysfunction are readily recognized in the clinical course of most patients with diabetes in whom early vascular degeneration is prone to develop.² On this basis, it would seem that diabetic persons who have evidence of vascular disease would benefit most from rigid control that would lessen stress and, consequently, support adrenal cortical function. Such rigid control is at least difficult in the ma-

From the Department of Medicine, The Charles T. Miller and University of Minnesota Hospitals, and the Department of Pathology, The Charles T. Miller Hospital, Saint Paul, Minnesota.

Dr. Wolff is Clinical Associate Professor, Department of Medicine, University of Minnesota.

Dr. Kennedy is Assistant Professor, Department of Medicine, University of Minnesota.

Dr. Johnson, former Senior Medical Resident at The Charles T. Miller Hospital, Saint Paul, Minnesota, is now practicing in Minneapolis, Minnesota.

jority of cases, a fact which gave stimulus to the thought that total bilateral adrenalectomy might modify the arteriolar degenerative lesions of diabetic patients.^{2,12,15} The fact that in Poulsen's patient, mentioned above, the hypopituitarism was marked initially by symptoms of severe hypoadrenalism lent further substance to this concept.¹⁵

Reports in the Literature

The first favorable result from bilateral subtotal adrenalectomy upon the vascular disease of a patient with malignant hypertension in association with severe diabetes mellitus was reported by Green and associates.^{16,17} Evaluation of this patient nine months and fifteen months after operation indicated that progress of the renal and other vascular lesions had been arrested. The patient's diabetes was improved greatly, with insulin requirements proportional to the amount of adrenal cortical extract administered. Subsequently, ten patients with diabetes mellitus and associated severe vascular disease treated by total bilateral adrenalectomy have been reported in the literature.

Wortham and Headstream^{2,15} reported a series of seven diabetic patients with retinopathy and other evidence of advanced renal disease. Of this series, two patients showed postoperative remission of vascular degeneration as evidenced by minor reversal in retinopathy, return of blood pressure to normal, decrease of proteinuria and nitrogen retention, and clearance of edema. In two cases, there was no further progression of pathologic features but less consistent improvement. Another patient demonstrated initial minor evidence of improvement but died of adrenal insufficiency after leaving the hospital. Of the remaining two patients in their series, one died of a cerebral vascular accident four and one-half months after operation and the other died of pulmonary and myocardial infarction four months after operation.

Hamwi¹⁸ reported two cases in which clinical improvement was manifested by ability to work and disappearance of retinopathy and edema. He denied, however, any significant improvement in the stability of the diabetes in these patients.

Martin and Wilson¹⁹ reported the case of a twenty-eight-year-old housewife with diabetes and advanced renal disease who underwent total bilateral adrenalectomy. Postoperatively, the patient was controlled by oral use of cortisone and

DOCA given intramuscularly. Proteinuria failed to decrease in this patient but the urinary excretion of sodium increased. Malignant hypertension developed when 50 mg. of cortisone was given daily.

Fig. 1. (*above*) Advanced arteriosclerosis of the kidney. (*below*) Intraglomerular hyaline bodies in the kidney. From the Department of Pathology, The Charles T. Miller Hospital, St. Paul, Minnesota.

The patient died of adrenal insufficiency with hyperkalemia and rapidly ascending muscular paralysis when, in an attempt to relieve the malignant hypertension, the dose of cortisone was reduced from 50 to 25 mg.

We would like to report the case of another young diabetic patient with associated vascular disease who underwent total bilateral adrenalectomy.

Case Report

The patient was first admitted in December, 1952, for the treatment of a fracture of the right tibia and fibula. He was twenty-three years of age and had had diabetes for twelve years. Examination at this time revealed cotton-wool exudates in the left eye, a normal right eye, and a borderline blood pressure of 140/80. The urine disclosed 3 plus albumin and 4 plus sugar;

there were ten to fifteen erythrocytes and fifty to sixty leukocytes per high-power field in the sediment. The blood urea nitrogen was normal. The serum contained 2.8 gm. of albumin and 3.8 gm. of globulin per 100 ml. Several subsequent admissions were necessary for the continued control of his diabetes and for the treatment of acute hypertensive encephalopathic episodes that were confused with and at times accompanied by insulin reactions. These episodes were marked by blurred vision in the right eye and loss of vision concomitant with the appearance of microaneurysms and retinal edema in that eye.

Because of the episodic nature of the hypertensive crises, the presence of a pheochromocytoma was suspected and several tests were performed during the ensuing months. The regitine test usually gave negative results, but in May, 1954 a positive histamine diphosphate test was obtained, during which the patient's blood pressure rose from a basal level of 145/100 to 200/130 and there was simultaneous onset of severe bilateral frontal headache and retrobulbar pain. Further studies at the University of Minnesota failed to confirm the abnormal histamine test, but regitine tests were typical, showing a decrease of approximately 25 mm. of mercury in systolic and diastolic blood pressure. Accordingly, the patient was explored for a possible pheochromocytoma on October 10, 1954. A tumor was not identified and, after thorough exploration, total bilateral adrenalectomy was performed in an attempt to prevent future hypertensive episodes and perhaps curtail further vascular degeneration.

Postoperatively, the patient was hospitalized on a number of occasions in an acute febrile state accompanied by sudden and severe hypotension necessitating additional adrenal cortical extract. His supportive therapy consisted of cortisone, 30 mg. daily, DOCA 2 mg. daily and 40 units of NPH insulin, which represented some decrease in his total insulin requirements.

Following these University Hospital admissions, he was again seen at Miller Hospital in hyperglycemic episodes accompanied by hypertensive encephalopathy. He was now given hydrocortisone orally and maintained on a split NPH insulin schedule of twenty-eight units every morning and eight units at suppertime.

Severe weakness of the extremities with apparent inability to move them voluntarily next ensued, and he was admitted on February 8, 1955, for treatment of this condition. Cortisone apparently possessed the ability to give him a feeling of normalcy. It was considered that he was suffering from hyperkalemia caused by hypoadrenalism, and this was substantiated by blood chemical studies, which revealed a blood sugar of 880 mg. per 100 ml., a blood urea nitrogen of 42 mg. and serum potassium of 9.6 mEq. per liter. Treatment with insulin, hydrocortisone and saline produced prompt remission of his symptoms.

His last outpatient visit occurred on May 31, 1955, at which time he complained of weakness, leg cramps early in the morning and easy fatigability of one week's duration, accompanied by anorexia, nausea and loose

stools. Blood studies the following morning showed the following: urea nitrogen, 40 mg.; serum chloride, 101 mEq. per liter; serum sodium, 135 mEq. per liter and serum potassium, 5.9 mEq. per liter. On the same evening, he continued to complain of anorexia and ate very little for supper. He did, however, visit with a friend and went for a ride, returning home about midnight, after which members of his family found him lying quietly in bed reading the newspaper; he stated he felt well. Approximately one hour later, he awoke screaming and immediately became comatose. He was brought to the hospital at 2 a.m. but was dead on arrival.

Immediately after arrival at the hospital, blood was drawn from the cardiac chambers and demonstrated a sugar of 1,286 mg.; values for serum chloride, sodium and potassium, respectively, were 92, 121 and 12 mEq. per liter.

Postmortem examination revealed extensive hyalinization of the glomeruli, with advanced arteriolosclerosis and scattered foci of lymphoid infiltration. There were also occasional intraglomerular hyaline bodies (Fig. 1).

At least twelve cases of total bilateral adrenalectomy in diabetic patients with advanced vascular disease have now been reported and there are certainly others not yet documented.²⁰ Of these twelve patients, five died postoperatively due to either adrenal insufficiency (three) or continued progression of the degenerative vascular lesions (two).

Conclusions

It appears that at least one reason for the unfavorable outcome of adrenalectomy in this series of cases lies in the advanced degree of vascular deterioration that always has been present before operation was considered. As a result, several authors have advocated that patients with evidence of severe vascular and renal deterioration, significant nitrogen retention, proteinuria in excess of 5 gm. daily and diastolic blood pressures more than 120 mm. of mercury should be excluded as candidates for adrenalectomy.

Consideration of total bilateral adrenalectomy as a therapeutic measure in the initial stages of arteriolar degeneration would appear to represent radical therapy, but it is evident that procrastination until the vascular or renal lesions have reached the stage of irreversibility has not been successful. As an ancillary procedure calculated to prolong life in a diabetic patient with advanced vascular disease, total adrenalectomy does not appear to deserve approbation.

SENSITIZATION TO BLOOD ANTIGENS

(Continued from Page 304)

transfusions, they do become important and can cause reactions.

Summary

1. Six cases are reported in which Rh₀ (D) positive persons have become sensitized by transfusion or pregnancy to one or more of factors rh" (E), hr' (c), Kidd (Jk^a), Duffy (Fy^a), P and Lewis (Le^a).

2. It is not correct to assume that only Rh negative patients are capable of becoming sensitized.

Acknowledgment

We are pleased to acknowledge the assistance of Drs. R. R. Race and Ruth Sanger, Blood Group Research Unit, Lister Institute, London, for confirming the serologic findings in cases 3, 5 and 6, and to Dr. T. J. Greenwalt, Milwaukee Blood Center, for confirming our findings in case 4.

Impending Occlusion of the Central Retinal Vein

VERNON L. LINDBERG, M.D.
Minneapolis, Minnesota

P. D., first seen at 1:00 p.m. on January 7, 1956, was a healthy white man, fifty-three years old. He stated that he awakened and noted blurred vision in his left eye the same morning. He was alarmed by this symptom and sought the advice of his ophthalmologist about noon of the same day.

At this time his corrected vision was found to be right eye, 20/20; left eye, varying between 20/50 and 20/100. The intraocular tensions were within normal limits. Examination of the left fundus revealed dilatation of the entire venous system of the retina. The veins were distended and dark blue in color. A small flame-shaped hemorrhage was noted on the temporal edge of the disc, and about six or eight other tiny punctate hemorrhages were seen. The right fundus was normal.

A working diagnosis of partial or impending occlusion of the central retinal vein of the left eye was made. The patient was immediately admitted to hospital and anticoagulant therapy was begun.

The following morning (January 8, 1956) at 10:30 a.m. he was re-examined, and at this time he stated that he believed the vision in his left eye had improved considerably. His corrected vision was found to be 20/20 in both eyes.

On examination the right fundus was normal, but the left fundus showed dilatation of the retinal veins, not as much as the previous day, but the veins were still definitely distended and bluish in color. The small retinal hemorrhages were noted as previously, but no new hemorrhages were seen. The patient was seen daily until his discharge from the hospital on January 17, 1956. Each day the visions were checked and found to be normal in both eyes.

Laboratory examinations, including occult blood in the stools, serology, hemoglobin, white blood count, sedimentation rate, blood cholesterol, blood fasting sugar, and urinalysis were all found to be negative or within normal limits. The electrocardiogram and chest x-rays were normal. The patient had pronounced varicosities in his right leg, but this was not considered significant.

On admission, a Lee-White clotting time and prothrombin time were obtained. Dicumarol was started with an immediate dose of 250 mg.; 175 mg. was given the second day, and thereafter the daily dosage was adjusted according to the prothrombin time.

Until the second day when the prothrombin time was twice that of the control, the patient's effective anti-

coagulant therapy was Depoheparin. This was begun immediately on arrival in the amount of 100 mg. intramuscularly. Within three hours the Lee-White clotting time was prolonged to twenty-four minutes, fifteen seconds; thereafter, the clotting time by this method was checked twice daily and if it was less than the desired range of twenty to thirty minutes, then 50 mg. of intravenous heparin was added.

The patient's prothrombin time was maintained between two and three times that of the control. Dicumarol therapy was continued ten days in the hospital until his dosage requirement was reasonably stable at 75 mg. per day. He was then discharged on ambulatory anticoagulant dicumarol therapy, with prothrombin time determinations made twice weekly for three weeks.

Corrected vision in his left eye on all office visits until the date of discharge, February 21, 1956, was found to be 20/20. On discharge, the left fundus showed complete absorption of all hemorrhages and the only positive finding was perhaps a slight dilatation of the venous tree of the left retina.

In the differential diagnosis, optic neuritis would have to be considered, but the therapeutic test definitely ruled this condition out. The fact that the condition was unilateral would tend to rule out the possibility of blood dyscrasia.

The fortunate outcome in this case depended largely on the fact that the patient was seen early in the course of his illness, and as a result specific therapy was introduced in time to be effective.

Writings on occlusion of the central retinal vein indicate that the prodromal symptoms of transitory obscurations of vision sometimes precede the complete stoppage of the central retinal vein by as long as weeks or months. This illustrates the fact that thrombosis of the central retinal vein is amenable to treatment if the diagnosis is made early (in contrast to occlusion of the central retinal artery where early emergency treatment is seldom effective).

Unfortunately, the usual results in this condition are poor. By the time the diagnosis is made in the average case, the central retinal vein has completely thrombosed and the retina is choked with massive round and flameshaped hemorrhages,

Presented at the annual meeting of the Southern Minnesota Medical Association, New Ulm, September 10, 1956.

Primary Cutaneous Myiasis

J. C. WOHLRABE, M.D.
Saint Clair, Minnesota

On August 6, 1956, a seventy-nine-year-old retired farmer came to my office in the evening complaining of bleeding. He had never been ill, never had any surgery, and in recent years had not traveled more than a few miles from his home in Blue Earth County, Minnesota. He had not been feeling well for several weeks and consulted me only because he feared that he might bleed to death.

The penis was bandaged in rags and blood flowed slowly from a 2 mm. opening in the left inguinal area at the base of the penis. There was erythema and induration for a radius of about 2 cm. around this opening. On further examination, four other lesions resembling furuncles were found on the medial aspects of the knees and thighs and one on the dorsum of the penis near the base. There was no extension of inflammation beyond the immediate area of each lesion. One of the lesions on the thigh was opened and a single maggot, 10 mm. long, was recovered. The patient was hospitalized, given penicillin and streptomycin, and scheduled for incision of the remaining lesions in the morning.

Laboratory findings were not noteworthy except for a leukocyte count of 12,100, with a differential of seventy-eight polymorphonuclear cells, one band cell and twenty-one lymphocytes.

Each lesion was opened. One additional larva was recovered. It was later learned that, while the orderly was preparing the patient for surgery, two larvae had emerged and were destroyed by him. Two of the lesions were apparently already vacated. To my knowledge, none contained more than a single maggot.

The two living maggots that had been recovered were placed in tubes containing small strips of beef and human muscle. One was mailed in this fashion to the Department of Entomology of the University of Minnesota for identification. The other was kept in its tube for two days and then it and the meat fragments were dumped into a fruit jar containing several inches of earth. After another day, it disappeared into

the dirt and was assumed to have formed a pupa. This jar was then also mailed to the University of Minnesota. Both specimens died (one went to the wrong office and was lost for several weeks). Positive species identification could not be made.

The patient's lesions healed uneventfully within a week.

Fig. 1.

The suggestion that this might be a case of *Wohlfahrtia vigil* was made. Reports have been made of primary bites in infants as far north as Toronto, Canada. To my knowledge, no cases of primary bites in adults have been reported in this area.

IMPENDING OCCLUSION OF THE CENTRAL RETINAL VEIN

(Continued from Page 322)

there is little, if any, collateral circulation in the retina and, as a result, complete thrombosis of the central retinal vein usually result in almost complete loss of vision. A late complication is the development of secondary glaucoma with frequent loss of the eyeball itself, because of the develop-

ment of a blind painful eye.

The symptom of transitory obscurations of vision in one eye, in a patient who has never had similar previous episodes of visual loss, should be treated as an ocular emergency until the real cause is established.

Continuation Study

Selection of Patients for Cardiac Surgery

PAUL ADAMS, M.D.
Minneapolis, Minnesota

THE MOST important function of the clinician and cardiologist on the cardiovascular team is the determination of the specific diagnosis or specific combinations of malformations that may be surgically treated. Rapid progress has been made in the area of diagnosis of congenital malformations of the heart by the use in recent years of angiocardiography, heart catheterization, and dye dilution techniques. The history, physical examination, electrocardiogram, x-ray studies and fluoroscopy still remain important considerations in arriving at the final diagnosis. The increasing number of malformations now amenable to surgical cure, and our realization that many of these malformations may produce death if undiagnosed and untreated at a few weeks or a few months of age, have extended the problem of diagnosis into comparatively unknown areas.

A simple generalization which has been helpful to me in understanding the complexities involved in selection of patients for cardiac surgery is to consider that each individual patient represents a balance or a gamble between the useful life expectancy and the gains expected and risks involved from surgery. The clinician's, surgeon's, and the parent's attitude toward these risks should be in reasonably close agreement.

One approach to determining the full life expectancy is to use the tables found in the literature stating the age at death from various specific malformations. The medium ages at time of death for a few of the common malformations are listed in Table I as reported by Abbott¹ and later by Edwards and Fontana.² Many of the values given are in remarkable agreement, others are completely divergent. The time of death is not the best point to judge the severity of a given defect. If a patient who lives to be forty years has been bedridden, handicapped, incapacitated for the past twenty years of his life, it is not to be considered

as adequate merely to extend the length of life. Rather the goal should be to eliminate the handicapping period preceding this and also to extend life expectancy.

TABLE I. LIFE EXPECTANCY OF PATIENTS WITH CONGENITAL MALFORMATIONS OF THE HEART

	Abbott Atlas	Edwards and Fontana
Atrial septal defect		
—Ostium secundum	34 years	50 years
—Below	19 years	
A-V canal		15 months
Ventricular septal defect	14 years	9 weeks
Patent ductus arteriosus	24 years	23 years
Pulmonary stenosis	22 years	23 years
Tetralogy of fallot	12 years	3 years
Transposition	2 years	8 weeks

A more helpful and realistic approach to the problem is to consider that each individual malformation or group of malformations has a spectrum of severity. It is now well known that children with a simple, correctable defect may die at a very young age even though the greater majority have a fair life expectancy and a very few may have a normal life expectancy. Figures available from our own State Department of Health and from other centers indicate that the statistical chance for survival of an infant with a malformation of the heart for more than one year if untreated is only 50 to 60 per cent. Because patients with surgically curable defects are dying at an early age we now realize that the greatest source of salvage of life is in the infant age group. A few of the helpful signs which indicate the urgent need for specific diagnosis and surgery at any age are listed below:

1. Early heart failure not responding to adequate medical therapy. Infants with coarctation of the aorta are a most frequent group of patients who fit into this group. Heart failure may often occur in the first few weeks of life and the aortic block may be successfully removed even at this early age.
2. Failure to gain weight adequately. To me this has

From the Department of Pediatrics, University of Minnesota Hospital, Minneapolis, Minnesota.

been a most helpful and objective finding indicating a markedly shortened life expectancy.

3. Frequent pneumonias which respond poorly to treatment. Occasionally a few infants with a very rocky course of repeated respiratory infections and

Fig. 1. "Curative" Procedure. Surgery indicated as elective procedure when diagnosis is established:

1. Patent ductus arteriosus
2. Coarctation of aorta
3. Vascular ring
4. Pulmonary valvular stenosis (Broch procedure)
5. Cor triatriatum
6. Tumor

a failure to gain weight during the first year of life will unexpectedly show dramatic improvement and be relatively free of difficulty for the next several years. Unfortunately, there is no good way of predicting which children will do this and, because they are in the minority, the findings of poor weight gain and repeated infections must remain an important indication for early diagnosis and surgery.

4. Cardiomegaly and progressive pulmonary hypertension are always alarming. In the present state of our knowledge, it appears that pulmonary hypertension may advance to equal the systemic pressure and that surgery may still be carried out with a reasonable hope of survival. However, once the pulmonary pressures have exceeded the systemic pressures so that the patient is now shunting right to left and exhibits either transient or constant cyanosis, surgery appears to be definitely contraindicated because this finding appears to represent a definite progression of pulmonary disease to the point where it is irreversible, and survival from surgery is impossible.
1. Marked dyspnea or increasing frequency and severity of cyanotic episodes. This is mentioned in connection with the diagnosis of pure valvular stenosis with intact ventricular septum and tetralogy of Fallot, since the above mentioned indications are less frequently found in these malformations.

On the other side of the balance, the risks of surgery and the gains expected must be evaluated. The risks of surgery may be expressed as mortality rates, but this fails to take all facts into considera-

tion. For example, if good risk patients only are operated upon, mortality rates are low. Poor risk patients are then permitted to die without any surgical attempt at helping them. If, on the other hand, no patient with a correctable malformation is refused surgical help regardless of the young age or physical condition, then mortality will be higher. However, if there are any survivors, then the overall number of patient years of life salvaged will have been greatly increased. This has been the aim of the cardiovascular team at the University of Minnesota. The term "salvage" is therefore used in the illustrations that follow rather than "mortality."

Surgical procedures may be roughly grouped into three categories depending on the gains that may be expected: (1) curative procedures, (2) palliative procedures, and (3) developmental procedures with unproven results.

Figure 1 will serve to illustrate the important relationships of the gains expected and the risks of surgery in the selection of patients. This balance represents the surgical procedures which may be reasonably considered to result in a cure. In the malformations listed in this group the overall life expectancy is predominantly good and symptoms are often entirely absent or minimal. Nevertheless, there are probably 5 or 10 per cent of patients with these curable malformations who will not survive the first year of life, if untreated.

In general, curative procedures involve a greater salvage or lower mortality than palliative or developmental procedures. This may be explained on the supposition that following the procedure the patient has a more nearly normal heart with which to help him recover through the critical postoperative phase.

Therefore, even though the patient may be asymptomatic, surgery is still strongly considered as an elective procedure as soon as the diagnosis is made. Procedures for the malformations listed, namely, vascular ring, pulmonary valvular stenosis, cor triatriatum, and certain cardiac tumors, are not as clear-cut curative procedures. Surgery may be recommended in such instances in the absence of clinical symptoms, but various degrees of abnormal physiologic findings should be present. For example, in pulmonary valvular stenosis the right ventricular pressure should be markedly elevated into the neighborhood of 100 mm. of mercury before surgery is considered.

Figure 2 illustrates the process of thinking in the patients where only palliative surgery is available. Here you will notice that the salvage rate is generally less favorable and the fact that palliation

Fig. 2. Palliative Procedure. Surgery indicated when handicapping symptoms or findings appear:

1. Tetrad (Blalock-Taussig)
2. Nonfunctioning right ventricle
3. Mitral stenosis
4. Aortic stenosis—transventricular—retrograde
5. Single ventricle (artificial pulmonary stenosis of Muller)

only is obtained carries less weight toward indicating surgery in such patients. Newer and better techniques may be available within a few months or a few years so that delay as long as it appears to be reasonably safe seems indicated.

Figure 3 illustrates the philosophy that is concerned with new and developmental procedures. You will notice here that the weights indicating surgery are of more questionable significance and, therefore, the indications for surgery in such instances are in people who have an extremely poor life expectancy. This obviously places the surgeon at a disadvantage. The surgeons in our institution have gladly accepted this philosophy. If an end-stage patient has been brought successfully through surgery, this is very impressive to the clinician and the balance may rapidly swing after a certain number of cases over toward the first or second categories that have been illustrated.

In conclusion, I would not feel right if the most important single factor involved in the final decision for surgery were not mentioned. Unfortunately, in such a discussion it is often most neglected or passed over too lightly. This involves the attitude of the parents toward surgery. The line of least resistance would be for the physician to assume full responsibility. Many parents would rather have someone else make such an important

choice. This tendency must be conscientiously and emphatically avoided in the ideal situation. To avoid this, our procedure has been to diagram, to explain, and to discuss the diagnosis with the par-

Fig. 3. Developmental Procedure. Surgery indicated only when life expectancy is poor:

1. Atrial septal defect
 - (a) Hypothermia
 - (b) Gross atrial well
 - (c) Bailey septo-pexy
2. Ventricular septal defect
 - (a) Cross-circulation—(now obsolete)
 - (b) DeWall bubble oxygenator
 - (c) Gibbon pump
3. Tetralogy of Fallot
4. Infundibular pulmonary stenosis
5. Pulmonary valvular stenosis—retrograde
6. Ostium primum syndrome—A-V canal
7. Transposition of great vessels
8. Total anomalous pulmonary venous drainage
9. Endocardial fibrosis—talcum in pericardium

ents. The life expectancy is discussed. The type of surgery, the risks, and expected results are outlined. Parents are then given as much time to make their decision as they require. They often discuss this with their family doctor, the other members of their family, their religious counselor and with the patient, in the case of older children. If the final decision is to have surgery, they then ask the surgeon to proceed. There should be no feeling of having been pushed into the decision against their better judgment. This approach, we believe, creates a more healthy psychologic attitude for both the physician and parent, regardless of the outcome of surgery.

CRIMINAL RESPONSIBILITY

Recent psychiatric and legal literature seems to reflect an ever-increasing interest in, and concern with, the matter of criminal responsibility. Generally, the articles that have been published in both legal and psychiatric journals have been critical of present laws governing criminal matters and, in particular, have expressed dissatisfaction with the outmoded M'Naghten Rule. The question of responsibility in criminal behavior is an important matter and one that merits more consideration, especially by psychiatrists and other physicians who are concerned with examining people charged with crimes.

Like many customs and laws, our present ideas about criminal responsibility are rooted firmly in tradition. In Great Britain 114 years ago, Daniel M'Naghten made an attempt on the life of the British Prime Minister, Robert Peel, but mistakenly killed Edward Drummond, the Prime Minister's secretary. At the trial, the defendant through his counsel, Alexander Cockburn, pleaded not guilty by reason of insanity. The jury, after hearing all the evidence including the testimony of nine medical witnesses, all of whom testified that M'Naghten was insane, found the defendant "not guilty, on the ground of insanity." Although the trial was fair and there seemed little doubt that M'Naghten was insane, the acquittal caused unrest in the population. People found it impossible to believe that the murder had resulted from M'Naghten's mental illness. Even Queen Victoria protested the decision. Eventually, the House of Lords, under the influence of the Crown, asked fifteen English judges to give their opinions on the law governing such cases. After taking the matter under advisement, their collective opinion was to the effect that an accused was not responsible if he was "labouring under such a defect of reason, from disease of the mind as not to know the nature and quality of the act he was doing; or, if he did know it, that he did not know he was doing what was wrong."

This collective decision rendered by the fifteen British Justices became known as M'Naghten's

Rule. It is more popularly referred to as the "Right-or-Wrong Test" and forms the basis of insanity as a defense in criminal matters in most English-speaking countries and in nearly all of the states in this country, including Minnesota. It is this rule which has largely shaped our present legal concepts of criminal responsibility. However, most serious students of the subject—legal, judicial, or psychiatric—regard M'Naghten's Test as an arbitrary, inflexible rule with little positive relationship to psychiatric or scientific fact. In actual practice, it is difficult and oftentimes impossible for the psychiatric or medical witness justly and honestly to present his findings and opinions within the rigid and restricted framework of the Right-or-Wrong test. For one thing, almost anyone except a person with extreme mental deficiency or severe delusional or regressive psychosis can distinguish right from wrong in some measure, and such cases seldom ever come to trial. What is needed is a new law which does not force the psychiatrist or medical expert to confine his testimony to the narrow limits of the Right-or-Wrong Test (which is really a moral, not a psychiatric decision) but allows him to report fully his evaluation and opinions. He should not be forced to make a "legal" diagnosis of mental illness on the basis of one symptom, any more than a pathologist or internist should be compelled to make a "legal" diagnosis of malaria on the basis of temperature alone.

Recently, there have been some breaks with the M'Naghten tradition, notably in Washington, D. C., where in the Durham case the court held that the old rule was no longer adequate. Instead, it was ruled that an accused is not criminally responsible if his unlawful act was the product of mental disease or mental defect. It is to be hoped that other jurisdictions, including our own state, will soon consider adopting laws which recognize the need to revise and modernize existing formulae and statutes so that they will conform to present-day psychiatric knowledge.

CLARENCE J. ROWE, M.D.

DANGLE

When you acquire a bit of freedom from the pressure of assuring food, clothing, and shelter for you and yours, then you have leisure. And leisure is what it takes to indulge in contemplative thinking. A philosopher* tells us that useless knowledge also contributes to the habit of contemplative thinking; indeed, that that may be the only worth of useless knowledge. We keep hearing about how people of this modern age are in such a headlong hurry that they never take time for contemplative thinking. So maybe you should expend this leisure on some contemplative reveries of the past: Have you gotten what you want out of life? Have you lived your life thus far? What in your nature has brought you pleasure and what displeasure? What would you change if you had it to do over again? Or, if that is too painful, maybe you should plan—or even *scheme*—for the future. How can you acquire more leisure? What are you going to do with it?

To you who contend that you have no leisure, we can only quote the earthy comment of an observant dentist who states categorically that *a man will do what he wants to do*. So don't try to squirm out of this problem by saying to yourself you have no time to spare.

All this sounds good. Take a trip to Europe *next* summer. Get a hunting group together *next* fall. Take off every week end to attend football games *next* season. Wonderful ideas, and a certain amount of day dreaming about the future is indeed pleasure in the present. But look about you for an instant. Here you are in the present, in a respected position in your community, the source for guidance and critical advice to your patients, productively busy yet with enough leisure to be reading an editorial page. Plenty of cause for happiness, without regard for the past or future, exists in the here and now.

All in all, man is so occupied with the ties that bind him to the past and the future that he fails to pause often enough to enjoy the present. We see no reason to remind physicians that life is not a static thing, that it is in a state of flux. But we *do* see reason to remind you that you will

never again be able to dangle your feet in this same water in the stream of time, so start dangling—enjoy the present.

H.G.M.

CONFESSIONS OF A HOBBYIST

In one of his essays on education, the late Dean Briggs of Harvard has written: “. . . every specialty is better mastered, better understood in relation to human life and achievement, by the man who has worked hard in other subjects. I believe the ἔργον,* or job, is the better for the πάρ-ἔργον,* or side-job.” This would seem to express, perfectly, the value of some manifestations of versatility—in a word, hobbies. In writing of my own, I cannot but be autobiographical. My own specialty—job—great hobby—has been school-mastering. For forty-four years, I had a certain amount of responsibility for the lives of a great many young people, and not a few who were not so young. The load, taken seriously, was not light. Some people can find escape in games. It was not so with me. I could go right through an active game of tennis, still painfully conscious of the troubles of some boy, parent or master. But once start working with my hands, and I was in another world. Not only have the various side interests relaxed the tensions of responsibility; they have also brought many points of contact with kindred spirits, young and old, in various fields and in various walks of life.

My varied interests have included stamp-collecting, the study of music, radio construction, cabinet-making, amateur botanizing, color photography, fishing, and, of all things, baking. This may make me appear a jack-of-all-trades, and master of none. Perhaps I am. Who ever mastered anything, anyway? The true hobbyist cannot but be a frustrated perfectionist. He wants to do things so well, and simply cannot catch up with perfection. Perhaps Browning was right when he wrote, “Ah, but a man's reach must exceed his grasp, or what's a Heaven for?”.

However that may be, I am going to write, briefly, of my own—one man's experiences and adventures with hobbies, for what it may be worth to other hobbyists.

JOHN DEQ. BRIGGS

*A chaplain, friend of ours, once defined philosophy as a midnight search in an unlit room for a black cat; and theology as a midnight search in an unlit room for a black cat that wasn't there.

(*In English type, “ergon and par-ergon”)

The next editorial by Mr. Briggs will tell of his stamp collecting hobby.

CALENDAR HISTORY

As the clock ticks off the minutes and hours, so the calendar will record the days and months with unfailing regularity until the end of time.

A day rarely passes that we do not glance at this infallible recorder that hangs on the wall or sits on our desk. We accept the calendar without question. We never mistrust its accuracy or reliability.

But research men for an advertising specialties firm which produces the bulk of the world's calendars, know the calendar that regulates our lives from birth to death was not always the obedient servant it is today.

Behind the calendar that hangs on the wall or sits on the desk lie centuries of research, confusion, adventure and romance all occasioned by man's countless attempts to nail down time to an accurate schedule of measurement.

Since the first cave man whacked at a handy tree with his stone axe to mark passage of one day, man has tried many ways to keep track of time accurately. But even in these prehistoric days, man dimly realized that the movement of heavenly bodies was the basis of timekeeping.

Astronomy, before men had identified it, was and is the thing on which all calendars rest. When the earth turns on its axis, it furnishes one unit of time—the day.

The revolution of the earth around the sun makes the year. The passage of the moon around the earth gives us the third unit—the month.

The problem of calendar making through the centuries has been to reconcile these three units of measurement. All of man's efforts have been directed at equalizing units so that by the end of the year, nature and man's measurement of time would come out even.

To keep track of nature's goings-on may sound simple. However, to measure these journeys of celestial bodies in the matter of minutes, even seconds, is a job for trained astronomers and other scientists.

Spring, we say, begins on the 21st of March. But this is just rough approximation. Just what second during that day—or the day before or after—does the vernal equinox make its visit?

A few minutes or hours doesn't sound like much in computing a year but even minutes can

pile up. After centuries, this mountain of minutes can cause extreme difficulties.

Brown & Bigelow

ALCOHOLISM IN INDUSTRY

Although alcoholism is receiving increased recognition as a health problem, there is still a tendency to believe that it happens only to someone else. This attitude also prevails in industry where the feeling often is expressed that, "Alcoholism is a serious problem—but not for us. We don't have any alcoholics." It has been reliably estimated, however, that at least 3 per cent of the average industrial work force will be alcoholics and that these employees will be found at all levels, from top management on down. This contradiction between belief and fact results from the hidden nature of the problem. Until its last stages, alcoholism shows no obvious signs. The alcoholic does his best to conceal his condition. He is often given very able assistance by the wife who makes excuses for his absences; by the fellow workers who do his work for him; by the supervisor who covers up for him, because he doesn't want to see him lose his job, or by the family physician whose medical terminology may hide the real problem.

An industry that is not sure it has an alcoholism problem might do well to analyze its attendance records, particularly those for Mondays and days following holidays. When an employe has a pattern of absences of this kind, it might be well to check further on his accident rate, over-all efficiency, and morale. In many cases, the results of such an analysis will reveal alcoholism as the basic problem.

When an industry starts investigating its alcoholism problem, it is likely to find that the average alcoholic employe will be a man, married and between the ages of thirty-five and fifty, who has been with the company for more than twenty years. The company will probably find that this man has had a good work record and is still a good worker . . . when he is on the job. Many alcoholics are highly skilled and, under ordinary circumstances, would be ready for key positions in the industry. It is obvious that industry cannot afford to lose such employes.

Second in a series of editorials on alcoholism in industry.

First of a series of seven editorials on calendar history.

Fortunately, more and more industries are taking steps to find out how much of an alcoholism problem they have and what they can do to rehabilitate the alcoholic employee. This interest is an outgrowth of industry's increased concern for employee welfare. However, it is also based on economic facts. With the acute shortage of trained workers in practically all fields today and with the high costs of training new employees, it is more important than ever for industry to take a close look at its policies regarding the alcoholic employee.

When the existence of alcoholism is recognized, rehabilitation is the next step. Industrial alcoholism rehabilitation programs have been conducted in a variety of ways. Some have depended solely on Alcoholics Anonymous; others have made effective use of community agencies; and still others have established programs of their own, utilizing AA counseling and company or community social services. Several large eastern concerns have found it profitable and effective to contribute toward the support of an alcoholism clinic to which their employees may be referred. It is extremely important, whatever type of program is conducted, that it have the sanction and support of top management. Without this, the program has little possibility of success.

PATRICK BUTLER, *Chairman
Minnesota Advisory Board
on Problems of Alcoholism*

RESPONSIBILITIES OF THE MEDICAL PROFESSION IN THE USE OF X-RAYS AND OTHER IONIZING RADIATION

1. The United Nations General Assembly, being aware of the problems in public health that are created by the development of atomic energy, established a Scientific Committee on the Effects of Atomic Radiation. This Committee has considered that one of its most urgent tasks was to collect as much information as possible on the amount of radiation to which man is exposed today, and on the effects of this radiation. Since it has become evident that radiation due to diagnostic radiology and to radio-therapy constitutes a substantial proportion of the total radiation received by the human race, the Committee

considers it desirable to draw attention to information that has been obtained on this subject.

2. Modern medicine has contributed to the control of many diseases and has substantially prolonged the span of human life. These results have depended in part on the use of radiation in the detection, diagnosis and treatment of disease. There are, however, few examples of scientific progress that are not attended by some disadvantages, however slight. It is desirable therefore to review objectively the possible present or future consequences of increased irradiation of populations which result from these medical applications of radiation.

3. It is now accepted that the irradiation of human beings, and particularly of their germinal tissues, has certain undesirable effects. While many of the somatic effects of radiation may be reversible, germinal irradiation normally has an irreversible and therefore cumulative effect. Any irradiation of the germinal tissues, however slight, thus involves genetic damage which may be small but is nevertheless real. For somatic effects there may however be thresholds for any irreversible effects, although if so these thresholds may well be low.

4. The information so far available indicates that the human race is subjected to natural radiation,[†] as well as to artificial radiation due to its medical applications, to atomic industry and its effluents and to the radioactive fall-out from nuclear explosions. The Committee is aware of the potential hazards that such radiation involves, and it is collecting and examining information on these subjects.

5. The amount of radiation received by the population for medical purposes is now, in certain countries, the main source of artificial radiation and is probably about equal to that from all natural sources. Moreover, since it is given on medical advice, the medical profession exercises responsibility in its use.

6. The Committee appreciates fully the im-

Statement by the United Nations Scientific Committee on the Effects of Atomic Radiation.

[†]The radiation due to natural sources has been estimated to cause between 70 and 170 millirem of irradiation to the gonads per annum in most parts of certain countries in which it has been studied, although higher values are found locally in some areas. See the reports "The hazards to man of nuclear and allied radiations" published by the United Kingdom Medical Research Council in June, 1956, in which also the millirem is defined; and from information submitted to the Committee.

portance and value of the correct medical use of radiation, both in the diagnosis of a large number of conditions, in the treatment of many such diseases as cancer, in the early mass detection of conditions such as pulmonary tuberculosis, and in the extension of medical knowledge.

7. Moreover, it appreciates fully the contribution of the radiological profession, through the International Commission on Radiological Protection* in recommending maximum permissible levels of irradiation. As regards those whose occupation exposes them to radiation, the establishment of these levels depends on the view that there are doses which, according to present knowledge, do not cause any appreciable body injury in the irradiated individual; and also on the consideration that the number of people concerned is sufficiently small for the genetic repercussions upon the population as a whole to be slight. Whenever exposure of the whole population is involved, however, it is considered prudent to limit the dose of radiation received by germinal tissue from all artificial sources to an amount of the order of that received from the natural background radiation.

8. It appears most important therefore that medical irradiations of any form should be restricted to those which are of value and importance, either in investigation or in treatment, so that the irradiation of the population may be minimized without any impairment of the efficient medical use of radiation.

9. The Committee is consequently anxious to receive information through appropriate governmental channels as to the methods and the extent by which such economy in the medical use of radiation can be achieved, both by avoiding examinations which are not clearly indicated and by decreasing the exposure to radiation during examinations, particularly if the gonads, or the foetus during pregnancy lie in the direct beam of radiation. It seeks, in particular, to obtain information as to the reduction in radiation of the population which might be achieved by improvements in instrument design, by fuller training of personnel, by local shielding of the gonads, by

choosing appropriately between radiography and fluoroscopy, and by better administrative arrangements to avoid any unnecessary repetition of identical examinations.

10. The Committee also seeks the co-operation of the medical profession to make possible an estimate of the total radiation received by the germinal tissue of the population before and during the child-bearing age. It considers it to be essential that standardized methods of measurement, of types at present available, should be widely used to obtain this information, and it emphasizes the value of adequate records, maintained by those using radiation medically, by the dental profession, and by the responsible organizations in allowing such radiation exposure to be evaluated. The Committee is convinced that information of this type will make it possible to decrease the total medical irradiation of the population while preserving and increasing the true value of the medical uses of radiation.

LETTER TO A YOUNG DOCTOR

My dear young Hippocrates,

I am addressing you in this way to remind you that you are *not* a creation of the 1948 National Health Service. You were born in the Aegean in the fifth century before Christ, and because of this it seems almost unnecessary for me to talk to you, for you already know from your student days that the precepts that govern your behaviour as a doctor have their origins in the mists of time. All the same, they are as strong today as throughout the ages. Since the beginning, our first duty has been towards our patients, to be at the same time their servants and their trusted friends. No National Health Service, no government by rules and regulations, no employment by the state, must ever be allowed to interfere with this traditional relationship: your job is to be a doctor first and a government servant afterwards.

I am, as you know, a family doctor. Forgive me, therefore if I say how much I hope you will enter this sphere of medical practice. Don't be put off by the term "general practitioner." Many of us dislike it. We prefer to be thought of and talked about as family doctors.

What type of man is this family doctor? I'm afraid you won't have heard much about him

*See the report of the International Commission on Radiological Protection (published in the *British Journal of Radiology*—Supp. 6, of December, 1954—in the *Journal français d'électro-radiologie*—No. 10, of October, 1955—etc. and revised in 1956).

Reprinted by permission from *The Listener* (England).

in your teaching hospital, for only the most advanced have yet got down to training their students particularly for general practice. Obviously this is a disadvantage. I well remember when I first left the security of my ancient hospital (in which I had been protected by the ward sister, bless her, the registrar, the assistant, and the senior physician) and found myself *alone* in general practice. I was armed with a book of my hospital's favourite prescriptions, and some hasty notes as to which should be used for what diseases. I also had that knowledge of human nature usually to be gleaned from six years of undergraduate existence, and the idea that because I'd satisfied my examiners I could also satisfy my patients.

To such a man are thousands of individuals entrusting themselves every day, and both patient and doctor are inwardly most apprehensive: the patient less so than the doctor, for he at least may have learnt what is wrong with him from his previous medical advisor, and have a fair knowledge of the treatment he should be given. It is not beyond the bounds of possibility that he'll clasp the new doctor to his bosom, taking on a sort of "I-saw-him-first" attitude, and telling his friends that the new young doctor is all right and knows his stuff. He must be relied upon to do this. It is the only hope. Cast yourself at first upon your patient's mercy; never pretend to know more about his illness than he does. A well-trained patient will sum you up in a few minutes, and your future bread and butter will depend a great deal upon his judgment.

If you do this, your favourite book of prescriptions won't matter. New vistas will be opened up and, for the first time, you will see the full depth of the medical stage. You'll realise that throughout your life you will be expected to play the leading part, and that your performance will be critically watched by a large audience who will insist that you should be word and action perfect on every occasion. It doesn't take long to convert a newly qualified and comparatively ignorant doctor into a knowledgeable and efficient family physician, wise beyond his years. He soon becomes capable of dealing with any type of patient, any emergency and any unpredictable situation, but the uncertainty and the excitement never go. Each day is a new adventure, each patient a new problem, each birth a new triumph, and each death a new heartbreak.

Let me now add a word of warning. The man who goes into family doctoring and reckons he is going to make a success of it merely because he knows a text-book of medicine off by heart, or how to give a blood transfusion, is going to flop as from the first day of his arrival in practice. The qualities which go to make a good doctor do not appear in any text-books; they are not discussed in any university medical curriculum, nor are they in any book of prescriptions. I divide them into two groups.

Compassion and Understanding

The first is compassion, sympathy, and understanding. The ability to feel for and to be as one with the patient in his illness, and to get across to him that, once having consulted you, he is no longer alone in his struggle. This is the foundation on which all medical treatment is built. It is, one might say, the container into which the medicine is poured and from which it is taken. An atmosphere of indifference, a cross look, an unsympathetic word, a quick glance at the clock, a prescription written before the full story has been told, a failure to examine thoroughly, and the container is cracked and worthless, and nothing that is put into it will do the patient any good.

As the years go by, you will be introduced to more and more human problems. Tolerance grows and compassion is intensified. The words left unspoken in the history, conveyed, as it were, by the worried look, begging you to understand that more could be said if it did not entail possible disloyalty to a husband, wife, or child, lack of appreciation of the mother-in-law living on the premises, inability to cope with the housekeeping, and so on; the little human displays that have to be put up, the fences to hide poverty or unhappiness from neighbours; the deaths and separations in the family; all mixed with the happy things, such as births and weddings and younger-generation achievements. All these appear in the surgery sooner or later, wrapped up in some obscure form or another. The majority of them are crying out for compassion, sympathy, and understanding.

Often, treatment can stop after a display of one or more of these qualities, but more often one must look for ingredients to put into the containers, and here we come to our second group:

the all-important non-material agents, faith and hope. I am not mocking, as I'm sure you will realize, when I say you must explain to a patient why you are giving him a certain medicine. Over and over again I have noticed that a patient with more than one complaint will come back after a week or so with the wrong one cured unless a careful explanation is given to him at the beginning as to which one is being treated.

The specialist does not depend so much for his success on these agents; he relies more on the build-up you give him. You know the sort of thing: "You'll find him a bit abrupt, Mrs. Jones, but don't worry about that. He's incredibly clever, and he knows your sort of case inside out." Mrs. Jones carries with her to the hospital your sympathy and understanding, together with the faith and hope you have given her. She is delighted to share your confidence in this particular consultant, and she would positively *hate* him not to be abrupt. His very abruptness becomes part of the treatment she expects from him. In all this you'll be in difficulties when you first start practising. But you will get to know your patients quite soon—particularly if you make a point of delivering their babies, piloting the children through the infectious diseases, and the parents through all the crises which occur when two or three human beings are gathered together.

This brings us to the sort of work you may expect to do in general practice, and the first thing I would say to you in this connection is that you must not think that because you are a family doctor you are to work on a lower plane than your colleagues in hospitals, or in local-authority health departments.

You do not often need to shift the responsibility for the care of your patient away from yourself from the first stage of his illness to the last. You have medical officers of health at your disposal, together with radiologists, pathologists, and specialists of all sorts, all of whom will willingly attend a consultation with you in your patient's home. In addition, you have midwives and health visitors, and one particularly important member of the team 'round the patient's bed—the parish priest or his nonconformist colleague.

But remember that when you visit your patient and decide to look after him yourself, you will be seeing him only for ten minutes each day, yet he is going to be ill for the whole twenty-four

hours. In other words, do not just leave him with a prescription and a few words of sympathy. Arrange for the district nurse to call. Ask him if he wants a home help. In fact fix it so that the patient is able to recover from his illness without his family collapsing.

I could talk to you for hours about the various types of patients you will see. Let me mention only three groups. The first are those who will come to you and say, "Of course, doctor, I know this is due to my age." Woe to you if you ever agree! It is your job to keep your patients as fit and active as possible, in spite of their age. They may be getting breathless when they walk upstairs, or have pain in their calf muscles when they go out shopping; they may find it difficult to get their knees moving in the mornings, or their insides moving at all. Whatever their trouble is, make sure that they clearly understand that it is not owing to their age. If it is, it may well be your fault and not theirs. They should have been moved into a flat long ago; the physical medicine department should be attacking their muscles and joints, and the daily living department their homes; they should be busy losing a stone in weight, and the home-help service should be at hand to help with the cooking, the cleaning, and the shopping. (Only two days ago, for example, a patient told me she had taken her rheumatism to Dr. X and he had told her there was nothing more he could do about it. Both she and I were flabbergasted. From a family doctor such a remark is little short of heresy.)

Next there are the neurotics, who will take up so much of your time and who tend to give general practice a bad name. Yet they are so often charming people, sensitive, generous, perhaps over self-centred, solitary children, spoilt and coddled in past years when such extravagances were possible; unrealistic, maladjusted, and quite incapable of standing up to the rush and tear of modern life. Their greatest sin is that they take up too much of your time. But that is no excuse for an unsympathetic or irritable manner. Always try to have a few minutes to spare each day for the lonely person who just wants to be talked to, to be advised or—quite often—instructed. A dismissal after ten minutes of chatting is far more effective than a hurried prescription after two minutes of reproach. And remember that the neurotics will be either your best advertisement

or your worst. Willy-nilly they constitute the group of patients who talk the most. It is nice to arrange that they say the right things!

Finally, a number of patients will complain of a symptom or group of symptoms recognizable at once as resulting from chronic stress and strain. You will see several of these every day. For all of them you are expected to supply a remedy in the shape of a bottle of medicine or a box of tablets, while the stress and strain goes on. How can one put a rest, or a holiday with change of environment, into a bottle or a box? Yet it has to be done, for nearly all these patients are women. They are bearing the burden of the home, the meals, the children, and (in far too many cases) of earning an addition to the family income to pay for that little extra of housekeeping, or the instalments on the furniture, the television, or the car. If you tell a male patient to go to bed he will thankfully retire, but say the same things to his wife and she'll need at least a week's notice, and if you try to keep her in bed for too long, you will find that she has timed your next visit to a nicety, so that she is in bed for a maximum of two minutes before you arrive and thirty seconds after the car has driven away. (You have only to be a family doctor for a week or so to realise of what poor stuff we males are made!)

A Perpetual Student

Before I leave you, let me say two more things, very briefly. The first is that as a doctor you must think of yourself as a perpetual student. It is unfortunate that nowadays, because of money, you may be tempted to take on too many patients, and this is bound to cut down the time you have to spare for reading, research, attendances at post-graduate courses or on hospital ward rounds. Yet if you are to do justice to your patients, you must take every possible chance to learn more and to keep your knowledge up to date. And never forget that whether you are a family doctor, a hospital consultant, or a medical officer of health, you are at the same time a member of one great and noble profession, artificially divided into three parts by the health service, but essentially one if the treatment of the patient is to be 100 per cent successful.

As a doctor, you may grumble and be full of pious misery in the winter months, but you will

never be so happy as when full of self-pity, never so contented as when overworked, and never so miserable as when away from your patients and the all-absorbing drudgery of medicine.

RONALD GIBSON
General Practitioner

REHABILITATION IN PULMONARY TUBERCULOSIS

Settlement

There have been great changes in treatment and in Social Medicine since Varrier Jones set out to provide for the housing and work of the patient whose prognosis made the sanatorium only a half-way house to further breakdown. Although settlement is not, and never was, the whole answer, it is still the only one for a significant proportion of sufferers; for example, some 10 per cent of all admissions have colonized at Papworth in the past seven years. They have done so of their own choice, after showing by their treatment and training their ability to earn their living in continuing sheltered employment.

By arrangement with the Trades Unions, they are paid at a rate only two-pence per hour under the full rate for a master-workman in open industry; one half-penny per hour is added every year for the next four years. The married men are given houses in rotation as our finances permit. As these houses are at low rentals, and there is no expense in commuting, there is sufficient money available for the proper care of the family, for whom, under the terms of our Charter, work is found in our shops. The boys can do their full apprenticeship in any of our trades, and so fit themselves for outside employment. Every colonist can join a voluntary superannuation scheme in which his contribution is doubled by the management; he can therefore make provision for his retirement over and above the normal, statutory old-age pension, or for a lump sum to be paid to his wife should he pre-decease her.

These settlers are the real back-bone of the economy of Papworth. They are an encouraging example to the man who commences training with a feeling of insecurity. All money made from the sale of their products comes back to the village in wages, housing, machines and amenities; the Management Committee are unpaid directors. The families provide the necessary fit personnel

President's Letter

SOME FUNCTIONS OF THE STATE BOARD OF MEDICAL EXAMINERS

The Minnesota State Board of Medical Examiners has performed yeoman's service for the citizens of our state and for the science of medicine.

The board consists of seven physicians appointed by the Governor of Minnesota for seven-year terms, one term expiring each year, and it has as one of its duties the granting of licenses to practice medicine. It also has the obligation of seeing that physicians, once licensed, do not engage in "immoral, dishonorable or unprofessional conduct," as defined by the statutes of Minnesota, and that they respect and observe these statutes which are enacted by the Legislature of the State of Minnesota to govern the actions and conduct of physicians in this state.

For most physicians, these matters are no problem and cause no concern. When infractions of law and of ethical and moral conduct do occur and are brought to the attention of the State Board of Medical Examiners, the physicians involved are brought before the Board and are accorded a fair hearing. Investigations are made by the legal counsel of the Board and his associates who inquire into any and all reports of the misconduct of any physician. The results are laid before the Board for consideration. Thorough deliberation follows and, as a result, the physician may be absolved of the charges or reprimanded or suffer suspension or revocation of his license. The Board receives many complaints which, after thorough investigation, are found to be only imaginary grievances, and are disposed of by a thorough airing and open discussion with the person accused. Fortunately, real infractions of conduct are rare in the medical profession.

These activities represent but a few of the problems which come before the State Board of Medical Examiners. However, they are of prime importance.

The licensing of foreign-trained physicians has been one of the most difficult problems to confront the Minnesota State Board of Medical Examiners. Similar boards of other states have been challenged by this problem for many years. With the advent of World War II, it became an impossibility to validate the credentials and personal references of candidates for licensure from many foreign schools. Fraudulent diplomas from foreign countries have come to light in the United States, thus additionally complicating the situation.

On November 12, 1937, the Minnesota State Board of Medical Examiners adopted a resolution by which only graduates of Class A schools from Canada and the United States were admitted to practice in Minnesota. All these schools in the United States are subject to inspection by proper authorities of the American Medical Association. During World War II, many universities of Europe were devastated, and have not been restored in their entirety to this date. Medical education in Europe in general has not been comparable to that of the students in American schools. For instance, in 1947 there were 3,500 medical students at the University of Vienna, out of a total enrollment of 7,000. At the University of

Munich there were 4,000 registered in the medical school, with a waiting list of 3,000. It was common for American students who had failed in the United States to enroll in European schools without having to repeat the course in which they had failed.

After World War II, the United States was faced with the problem of relocating displaced persons. Many of them were physicians from various European countries. Under the Displaced Persons Act of 1948, more than 200,000 aliens came to the United States. In 1953, a second act was passed which was designed to admit another 209,000 nonquota refugees before December 31, 1956. Hence, in view of these statutes and the resolution which the Board adopted in 1937, as mentioned earlier, a conference on the advisability of licensing foreign physicians by the Minnesota State Board of Medical Examiners was held with Governor Youngdahl in January, 1949.

It has become extremely difficult under these conditions to evaluate foreign medical schools. Hence, the Minnesota State Board of Medical Examiners developed rules and regulations for the examination of applicants for licensure who came from schools outside the United States or Canada. In addition to requiring the applicant to meet the requirements of certain well-founded rules and regulations, the Board now interviews each foreign physician, and his problem is considered on an individual basis. At the time of his interview, he must present documentary evidence, properly authenticated, to prove that he has successfully completed a course equivalent to that given and required by the School of Medicine of the University of Minnesota, and that he has received the degree of bachelor or doctor of medicine or its equivalent. He must present evidence of good moral character, must be able to read, write and speak English, must possess evidence that he has successfully passed the examination of the Board of Examiners in the Basic Medical Sciences, and must have received a certificate of registration in the basic medical sciences. If the candidate can meet these requirements and can pass the Board's evaluation, then he is allowed to take a two-year internship in an accredited hospital in the State of Minnesota. Depending on his record as an intern, he may or may not be allowed to take the examination of the Minnesota State Board of Medical Examiners at the completion of his internship. These regulations have considerably improved the situation with respect to the licensure of foreign physicians. The number of applicants has diminished.

In view of the new influx of Hungarian displaced persons, it is possible that another wave of physicians seeking licensure in Minnesota will approach the Board, and that pressure will be brought from outside sources for the licensing of physicians without proper accreditation, as happened after World War II. However, on the basis of our experience in the past, we should be able to meet the situation in a more satisfactory manner than was possible some years ago.

Another closely related problem concerns postgraduate study on the part of physicians from other countries at the University of Minnesota and at the Mayo Foundation. We all agree that the process of training these physicians should be in the finest tradition of improving medical care for the mass of people throughout the world and that it should, at the same time, enhance friendly relations between the people of the United States and the people of other countries. Now,

this exchange of views also carries with it the implication that the Minnesota State Board of Medical Examiners ought to be better able than most other bodies or organizations in Minnesota to evaluate the type, extent and quality of medical education that has been obtained by physicians and surgeons in foreign countries. Hence, it would be reasonable to assume that the Minnesota State Board of Medical Examiners should assist in a fair and proper determination of approval or non-approval of the quality of medical education attainable in foreign schools. The Board has passed a resolution by which a limited number of foreign physicians and surgeons would be enrolled, for the sole purpose of graduate education in the University of Minnesota and in the Mayo Foundation at Rochester for a period of three consecutive years, or as otherwise determined. The primary purpose of such a course of study is to enable foreign physicians to further their graduate medical education and then to return to their native countries. This particular action is in no way intended to qualify these physicians for medical licensure in the State of Minnesota. If any of the physicians who have completed this special type of graduate study desire to apply for medical licensure in this state, their applications will be considered on an individual basis at the discretion of the Board, and the applicants must first comply with the regulations set forth by the Board.

An additional effort of the Board in this direction is the legislation recently introduced by the Board, and passed at the current session of the Legislature, to amend the Medical Practice Act so that temporary resident licenses can be granted to a limited number of residents in accredited hospitals in the State.

By January 1, 1957, 112 foreign-born physicians had been licensed by the Minnesota State Board of Medical Examiners. Of the 112 licensed, 50 have now become citizens of the United States.

The original purpose of this program of licensing foreign physicians was to improve the distribution of physicians in the State of Minnesota. It was the hope of the Board that these physicians would seek to practice medicine in the smaller communities, or in communities in which physicians are really needed. In practice, this desideratum has not come to pass.

It would seem, therefore, that only a small percentage of the foreign physicians licensed to practice medicine in Minnesota actually have established practices in the smaller communities of Minnesota. It is hoped that in the future this undesirable situation will be changed.

NEW BILLS FILED IN CONGRESS MORE HEARINGS SCHEDULED

Hill-Burton Amendment

A new measure sponsored by Senators Lister Hill of Alabama and Robert S. Kerr of Oklahoma amends the Hill-Burton Act to allow the government to make low interest *loans* as well as *grants* in support of hospital construction.

Humphrey Plan Revived

Ever since he became a Senator eight years ago, Minnesota's Hubert Humphrey has tried for passage of a bill authorizing Federal loans, long-term and low-interest, to assist voluntary nonprofit associations offering prepaid health services. Just recently, he put it in again and promised to press for favorable action in this 85th Congress. Hearings will be conducted by the health legislation subcommittee of the Senate Labor Committee.

Delay Asked on Disability Amendment

At the request of the Department of HEW, ranking members of the House Ways and Means Committee are sponsoring a bill amending Title II of the Social Security Act. It would extend for one year the deadline for disabled workers to apply for determination of disability preliminary to "freezing" of their benefit rights. Under the existing law, the time limit is June 30, 1957, but HEW believes that a year's extension is imperative because an estimated 165,000 eligibles have yet to apply for disability determinations.

Hearings

Hearings have been opened by the aviation subcommittee of the Senate Commerce Committee on S. 1045 which gives medical affairs a status in the Civil Aeronautics Administration comparable to that which they hold in the military and in the Veterans Administration.

The printed transcript of Congressional hearings held in March on the Department of HEW's budget is almost an encyclopedia of government medicine. It sheds new light on the Administration's views on health insurance, and it contains

technical descriptions of research conducted at the 500-bed Clinical Center at suburban Bethesda, Maryland. In the 1,602 pages of its two volumes, the transcript presents testimony and committee-men's comments on medical school subsidization, the deterioration of U. S. Public Health Service hospitals, the health of American Indians and many more subjects.

HIGHLIGHTS OF HEW BUDGET REVIEWED

The HEW budget (combined with that of the Labor Department) was reshaped by a subcommittee whose chairman was Representative John E. Fogarty (D., R. I.).

Among the highlights of the HEW budget are these:

Medical Research Assistance

For support of medical research, the House Appropriations Committee has recommended what the Administration asked—\$220,183,000. Of this total, \$30 million is for research construction grants; the bulk of the remainder would go to medical schools and hospitals for project grants, with substantial sums marked for the operation of the Clinical Center and intramural research at the parent National Institutes of Health.

Public Health Service Hospitals

For the first time in years, the full sum requested (\$44,399,000) was granted because of the grim picture painted of the obsolescence and maintenance shortcomings of these hospitals.

Hill-Burton Hospitals

For continuation of Hill-Burton hospital expansion grants, \$120 million was approved. This was exactly what the Administration requested, although the House group did some fund shifting.

Health Care of Indians

The sum approved for the construction of health facilities for Indians was \$3,096,000, a reduction of \$2,704,000 from the request. This was

justified on the basis of the fact that nearly \$12 million in carryover funds is still available for the construction of hospitals and clinics.

Health Aid to States

Stricken from the HEW budget was a \$1.5 million item for special project grants to the states in the field of chronic disease and aging.

NEW DOCTOR-DRAFT PLAN DUE FOR HOUSE HEARING

The Administration's proposed substitute for the doctor-draft law which expires in June was sent up to Capitol Hill early in April and promptly introduced as a bill by Representative Carl Vinson (D., Ga.). It is expected that it would be passed by the House with little delay following hearings scheduled by the Armed Services Committee. The only change which this bill makes in the existing law is to eliminate the 4-ply priority system. The President retains authority to call up physicians and dentists as and when needed by the armed forces.

However, the bill does neglect to continue the medical advisory committee to selective service headed by Dr. Howard A. Rush since its beginning in 1950. The American Medical Association and the American Dental Association will doubtless urge its retention.

MINNESOTA INCLUDED IN AWARD FOR RESEARCH BUILDING

The Public Health Service has approved the awarding of thirty-five grants to twenty-seven institutions, chiefly universities, to aid in the construction or improvement of research facilities. Three of the recipients will get more than one-half of the total: the University of Minnesota, Bowman Gray School of Medicine, and the University of Oklahoma Medical Center. A few of the grants are for the purchase of equipment. These are on a dollar-for-dollar matching basis, the same as the construction subsidies.

SUPREME COURT DECLINES TO SUPPORT NATUROPATHY

The U. S. Supreme Court reviewed and affirmed a lower court's judgment against a naturopath and his sympathizers who contended that Maryland's Medical Practice Act is unconstitutional because it makes no provision for the licensing of healers who follow that cult. The Court

handed down no written opinion. Also, recently, the highest tribunal turned down a petition to review a Utah court decision supporting the right of the state's Attorney General to withdraw from naturopaths licensing privileges to practice obstetrics and perform minor surgery.

These were not the first cases involving naturopathy to be considered by the Supreme Court at the current session, and they will not be the last. Its practitioners and their associations are particularly busy this year in the nation's courts as well as in legislatures, making determined bids for recognition as a healing art.

MORE TALK OF SOCIAL SECURITY FOR PHYSICIANS

As a sideline on social security for the professions, HEW says that more than one-half of the country's clergymen have exercised their option to be covered. April 15 was the deadline for their applications for inclusion. Congress members and committees continue to receive letters and petitions from individual physicians and medical groups requesting social security benefits for M.D.'s.

The pros and cons of the major issues involved in the proposed coverage of physicians were set forth at the annual meeting of the Providence (R.I.) Medical Association by a research associate of the Life Insurance Association of America and an authority on the old age and survivors insurance program. The speaker concluded that "the cons just about balance the pros" yet he felt there "is a bit more to be said in favor of OASI coverage for doctors than against it." He based his premise mainly on the economic factor—that OASI can be considered a "good buy" with the participants, on the whole, getting their money's worth.

In reviewing this analysis, the *Rhode Island Medical Journal* editorializes that "the analysis . . . is excellent from an economist's point of view but not from a physician's.

" . . . The big question of principle and philosophy that still remains unanswered and probably can only be answered by the individual physician is this:" states the Journal. "If the physician believes the federal government should compel him and every other citizen to pay into a tax fund to provide benefits for his old-age insurance and retirement and protection for his survivors in the event of an early death, then does he not have

to agree to the logical corollary that the government would be justified in taxing him and everyone else to provide medical care for all under a compulsory system?

"Before he consents to join any compulsory social security system," the *Journal* continues, "the question which he should thoughtfully consider is this: 'Am I willing to exchange my personal economic liberty for promises of material welfare?' Should the medical profession decide to surrender one liberty, it will surely be invited or even compelled, later on, to surrender others."

BRITISH M.D.'S CONTINUE TO CONSIDER WALK-OUT

Twenty-thousand British physicians are still threatening to pull out and go back to private practice unless they get a 24 per cent increase in the fees the government pays them. This latest difficulty for the program that was set up by a Socialist government back in 1948 is bringing to the surface a whole series of complaints. Lack of incentive for the medical profession, poor relationship with patients and a decline in ethical standards are a few of the things being debated by critics and supporters of the National Health Service.

Under the present system, family physicians get a lump sum annually for each patient. A doctor with a maximum list of 3,500 patients has a gross income of \$8,600 per year. Specialists receive flat salaries ranging from \$5,000 to \$8,700. In addition, they can qualify for "distinction awards" that go as high as \$7,000 for "special contributions to medicine, exceptional ability or outstanding professional work."

What the patient gets is complete medical care and hospitalization. The only things a Briton has to pay directly for are 14 cents each for prescriptions, \$2.80 for a full course of dental treatment plus nominal sums for false teeth, eyeglasses and medical appliances.

For the government, the steadily rising cost of socialized medicine is causing great worry. Ever since the system was created, the bill has been going up. By 1950, it was \$1.2 billion a year. In the next budget, it will be around \$2 billion. Now the doctors who want a raise are forcing everyone to take a close look at socialized medicine after nearly ten years of trial.

What the examination shows is this: The program is more expensive than anyone expected.

There is a lot of grumbling among doctors about being underpaid, overworked and forced to neglect advances in their profession since they are encouraged to send unusual cases to specialists. Said a British Medical Association official: "General practitioners are becoming men who merely dole out pills and tranquilizers."

Now the M.D.'s say that if the government fails to satisfy their demand for a 24 per cent pay increase, they will make a "progressive withdrawal" from the Health Service. On October 2, GP's in "selected areas" will resign from their local medical lists. During October, former NHS patients will be treated free but starting November 1 patients will be charged a standard "token fee," probably about 70 cents for a consultation and about \$1.05 for a home visit. Later, as more GP's withdraw from the service, a "full economic charge" for the doctor's work will start.

STATISTICS ON OBSTETRICAL COSTS, HOSPITAL OCCUPANCY

Obstetrical Costs

A recent release from the Health Information Foundation comes as a welcome change from the usual reports of increasing medical costs. Having a baby is not only safer today than it was twenty-five years ago, but measured in equal dollars, it is also 18 per cent less expensive. Total obstetrical care during the 1928-1931 period averaged \$258 in terms of the present day dollar. In 1953, total obstetrical care averaged \$213. These figures are all the more significant considering the cost of all medical care when one realizes that seven per cent of hospital admissions in 1953 were obstetrical admissions.

According to the Foundation, Americans have consistently spent approximately the same proportions of their expendable incomes—4 to 5 per cent—for medical care each year for the past twenty-five years. Yet a much broader range of diagnostic and treatment facilities is now available to more people than ever before, for the same relative cost.

Hospitals

Occupancy of beds in eleven Minneapolis-area hospitals was "well above" the recommended rate in March. On an average day, 21,149 patients were occupying beds at the hospitals. This is 93 per cent occupancy, well above the 75 to 80 per

(Continued on Page A-36)

Meetings and Announcements

STATE

MINNESOTA STATE MEDICAL ASSOCIATION, 104th annual meeting, Saint Paul, May 13, 14 and 15, 1957.

Minnesota Society of Internal Medicine, spring meeting, May 25, at Red Wing.

NATIONAL

American Congress of Physical Medicine and Rehabilitation, thirty-fifth annual scientific and clinical session, Los Angeles, September 8-13, 1957.

American Goiter Association, Hotel Statler, New York, New York, May 28-30, 1957. John C. McClintock, M.D., Secretary, 149½ Washington Avenue, Albany 10, New York.

American Association of Rehabilitation Therapists; Association for Physical and Mental Rehabilitation; Association of Medical Directors and Co-ordinators, Chicago, July 7-12.

Canadian Pediatric Society, Winnipeg, Manitoba, June 12-15, 1957. (Held in conjunction with the scientific opening of the Winnipeg Children's Hospital and with the Northwestern Pediatric Society.)

The Children's Hospital of Philadelphia. Three short refresher courses. "Pediatric Advances for Pediatricians and General Practitioners," May 27-31, 1957. "Practical Pediatric Hematology," June 3-5, 1957. "Blood Group Incompatibilities and Erythroblastosis Fetalis," June 6-7, 1957. Irving J. Wolman, M.D., Children's Hospital of Philadelphia, 1740 Bainbridge Street, Philadelphia 46, Pennsylvania.

New York University Post-Graduate Medical School. Management of Chronic Kidney Diseases, June 24-25, Dr. Lawrence G. Wesson. Office of Associate Dean, New York University Post-Graduate Medical School, 550 First Avenue, New York 16, New York.

New York University Post-Graduate Medical School. Management of Hypertension, June 26-27, Dr. J. Marion Bryant. Office of Associate Dean, New York University Post-Graduate Medical School, 550 First Avenue, New York 16, New York.

Ninth Postgraduate Assembly in Endocrinology and Metabolism, Medical College of Georgia, October 21-25, 1957.

Symposium on Tuberculosis and Other Chronic Pulmonary Diseases, Saranac Lake, New York, July 8-12, 1957. Sponsored by the American Trudeau Society, Saranac Medical Society, Adirondack Counties Chapter of the New York State Academy of General Practice. Write P. O. Box 11, Saranac Lake, New York.

University of Pittsburgh School of Medicine, Department of Surgery, Section of Anesthesiology—Post-

graduate Symposium on the Basic Sciences Related to Anesthesiology, June 10-14, 1957. Write to Chairman of the Committee on Graduate Medical Education, University of Pittsburgh School of Medicine, 3941 O'Hara Street, Pittsburgh 13, Pennsylvania.

INTERNATIONAL

Canadian Medical Association, Edmonton, Alberta, Canada, June 17-21. Dr. A. D. Kelly, 150 St. George Street, Toronto 5, Ontario, Canada.

Congress of International Association for Study of the Bronchi, Lisbon, Portugal, May 25-26. Prof. F. Lopo de Varvalho, 138 rua de Junqueira, Lisbon, Portugal.

Congress of International Society for Cell Biology, St. Andrews, Fife, Scotland, August 28-September 3. Prof. H. G. Callan, Bell Pettigrew Museum, The University, St. Andrews, Fife, Scotland.

Congress of International Society of Orthopedic Surgery and Traumatology, Barcelona, Spain, September 16-21. International Society of Orthopedic Surgery and Traumatology, 34 rue Montoyer, Brussels, Belgium.

Congress of International Society of Surgery, Mexico City, Mexico, October 27-November 2. Dr. L. Dejardin, 141 rue Belliard, Brussels, Belgium.

Fourth International Poliomyelitis Conference, Geneva, Switzerland, July 8-12. Registration deadline, April 1. Fourth International Poliomyelitis Conference, Secretariat, Hotel du Rhone, Geneva, Switzerland.

Inter-American Congress of Pan American Medical Association, Mexico City, Mexico, November 18-22. Dr. Joseph J. Eller, 745 Fifth Avenue, New York 22, New York.

International Congress of Clinical Pathology, Brussels, Belgium, July 15-20. Prof. M. Welsch, Universite de Liege, 32 Blvd. de la Constitution, Liege, Belgium.

International Congress of Dermatology, Stockholm, Sweden, July 31-August 6. Dr. C. H. Floden, Karolinska, Sjukhuset, Hudkliniken, Stockholm 60, Sweden.

International Congress of Electroencephalography and Clinical Neurophysiology, Brussels, Belgium, July 21-28. Dr. R. G. Bickford, Mayo Clinic, Rochester, Minnesota.

International Congress on Medicine and Surgery, Turin, Italy, June 1-9. Secretariat, Minerva Medica, Corso Bramante 83-85, Turin, Italy.

International Congress of Neurological Sciences, Brussels, Belgium, July 21-28. Dr. Pearce Bailey, National Institutes of Health, Bethesda 14, Maryland.

International Congress of Neurosurgery, Brussels, Belgium, July 21-28. Dr. William B. Scoville, 85 Jefferson Street, Hartford, Connecticut.

International Congress of Neuropathology, Brussels, Belgium, July 21-28. Dr. Ludo J. Bogaert, 47 rue de l'Harmonie, Antwerp, Belgium.

International Congress of Nutrition, Paris, France, July 24-29. Congress International de Nutrition, 71 Blvd. Pereire, Paris 17e, France.

International Congress on Rheumatic Diseases, Toronto, Ontario, Canada, June 23-28. International Congress on Rheumatic Diseases, P.O. Box 237, Terminal "A," Toronto, Ontario.

International Gerontological Congress, Merano-Bolzano, Italy, July 14-19. Segreteria, Quarto Congresso Internazionale de Gerontologia, Viale Morgagni, 85, Firenze, Italy.

International League Against Epilepsy, Brussels, Belgium, July 21-28. Dr. Radermecker, Institut Bunge, 59 rue Philippe Milliot, Berchem, Antwerp, Belgium.

International Symposium on Medical-Social Aspects of Senile Nervous Diseases, Venice, Italy, July 20-21. Secretariate, Viale Morgagni 85, Firenze, Italy.

Neuroradiologic Symposium, Brussels, Belgium, July 21-28. Professor Melot, Hôpital Universitaire St. Pierre, Brussels, Belgium.

Pan-Pacific Surgical Association, seventh congress, Honolulu, Hawaii, November 14-22, 1957. Write Dr. F. J. Pinkerton, director-general of the Pan-Pacific Surgical Association, Room 230, Young Building, Honolulu, Hawaii.

Third International Medical-Surgical Meeting, Torino, Italy, June 1-9, 1957. Includes four international congresses (International Congress on Nuclear Medicine, International Congress on Photobiology, and International Congress on the Problems of the Goitre), seven national congresses (on chemotherapy, gastroenterology, surgery), ten symposia (European Society of Cardiovascular Surgery, Symposium on Artificial Heart-Lung Machines), and many meetings on the various medical and surgical specialties. Write: Secretary-General, Minerva Medica, Corso Bramante 83-85, Torino, Italy.

William Harvey Tercentenary Congress, Royal College of Surgeons, London, England, June 3-7, 1957. Dr. D. Geraint James, Harveian Society of London, 11 Chandos Street, Cavendish Square, London W. 1, England.

AMERICAN COLLEGE OF PHYSICIANS TO HOLD POSTGRADUATE COURSES

Forthcoming postgraduate courses to be held by The American College of Physicians are as follows:

Internal Medicine—May 13-17, 1957, University of Chicago, Department of Medicine, Chicago, Illinois. *Meeting Place:* Albert Merritt Billings Hospital, 950 East 59th Street, Chicago 37, Illinois, Room P-117.

Early Prevention and Detection of Disease—May 20-24, 1957, University of Pennsylvania School of Medicine, Department of Public Health and Preventive Medicine, Philadelphia, Pennsylvania. *Meeting Place:* Auditorium, American College of Physicians, 4200 Pine Street, Philadelphia.

Internal Medicine—May 20-24, 1957, Louisiana State University School of Medicine, Postgraduate Division, Shreveport, Louisiana. *Meeting Place:* Confederate Memorial Hospital.

Cardiology—May 27-31, 1957, The National Institute of Cardiology of Mexico, Mexico, D. F. *Meeting Place:* The National Institute of Cardiology, Lecture Room "A."

Internal Medicine—May 27-31, 1957, New York University Post-Graduate Medical School, New York, New York. *Meeting Place:* Medical Science Building, New York University-Bellevue Medical Center, 550 First Avenue, New York.

Ballistocardiography—June 10-12, 1957. *Meeting Place:* Hospital of the University of Pennsylvania, Philadelphia, Pennsylvania.

LECTURE ON HEMOPHILIA

The Minnesota Chapter of the National Hemophilia Foundation will present a lecture by Dr. Kenneth M. Brinkhous, Professor of Pathology, University of North Carolina, on the subject of "Hemophilia," on Friday, May 24, 1957, at 8:00 p.m. in the Mayo Memorial Auditorium of the University of Minnesota. The University of Minnesota Medical School is co-sponsoring this event to which all medical personnel are invited.

CONTINUATION COURSES

Medical continuation courses to be presented at the Center for Continuation Study, University of Minnesota, include the following:

- May 6 -10 Introduction to Electrocardiography for General Physicians
- May 13-17 Proctology for General Physicians
- May 23-25 Surgery for Surgeons

For further information concerning the above courses, write to the Director, Department of Continuation Medical Education, 1342 Mayo Memorial, University of Minnesota, Minneapolis 14.

Woman's Auxiliary

NATIONAL CONVENTION

Announcement has been received of the program of the Woman's Auxiliary to the American Medical Association at its thirty-fourth annual meeting to be held in New York City, June 3 to 7. Headquarters for the Auxiliary's meeting will be the Hotel Roosevelt, Madison Avenue and 45th Street, within walking distance of the Waldorf-Astoria Hotel, where the AMA's House of Delegates meets, and close to shopping centers and theaters.

The general meeting will be held on Tuesday, Wednesday, and Thursday, June 4 to 6. On Monday, June 3, and Wednesday afternoon, June 5, round table discussions of interest and educational value to all physicians' wives will be held. A post-convention workshop for state presidents, presidents-elect and national committee chairmen will be held on Friday, June 7.

Social activities include a tea on Monday, June 3; luncheon on June 4 at which Dr. Howard Rusk, director of the Institute of Physical Medicine and Rehabilitation of the New York University-Bellevue Medical Center, will be the guest speaker; luncheon, Wednesday, June 5, at which the guest speaker will be Dr. Dwight H. Murray, president of the American Medical Association; and the annual dinner for auxiliary members, husbands and guests, Thursday, June 6, at which the guest speaker will be Professor Allen Richard Foley of Dartmouth College.

NEWS FROM THE COUNTY AUXILIARIES

Goodhue

The Woman's Auxiliary to the Goodhue County Medical Society recently voted to be an active organization again. Mrs. Royal Sherman, Red Wing, is press and publicity, newsletter and MINNESOTA MEDICINE chairman. The group has published a most attractive program for the year, entitled "The Minnesota Gopher Doctor's Wife." The cover was done by a former patient at Mineral Springs Sanatorium in Cannon Falls and the contents were produced by a handicapped lady from near Zumbrota.

Officers for 1957 are Mrs. Ezra V. Bridge, president; Mrs. George Hawley, vice president, and Mrs. John Falls, secretary-treasurer.

Mrs. James Halvorson and Mrs. Marland Williams are on the program committee for 1957; Mrs. William Liffbrig and Mrs. Edward Juers for 1958. Mrs. Winston Miller is in charge of membership and legislation and Mrs. James Brusegard, Mrs. Samuel Hamilton and Mrs. Clarence Wasmund make up the social committee. Other committees include: ways and means, Mrs. Raymond Hedin, chairman, Mrs. Oliver Larson and Mrs. Willard Akins; cancer, Mrs. Grant Hartnagel; mental health, Mrs. Oliver Larson; mentally-retarded children, Mrs. Leon Steffens; allied medical careers, Mrs. James Halvorson; medical and surgical relief, Mrs. William Walter; program and health education, Mrs.

Robert Molenaar; public relations and health days, Mrs. Edward Juers; *Today's Health*, Mrs. Clarence Wasmund; AMEF, Mrs. Samuel Hamilton; civil defense, Mrs. George Kimmel; tuberculosis, Mrs. Ezra V. Bridge.

Programs for the year include these: in January, the group met at the St. James Hotel in Red Wing. Guest speaker was Allan Stone, executive director of the Minnesota Division of the American Cancer Society.

The February meeting was held at the Mineral Springs Sanatorium. Dr. Ezra V. Bridge, medical director and superintendent of the sanatorium, spoke and conducted Auxiliary members on a tour.

In March, the Auxiliary met for luncheon at the St. James Hotel. The morning hours were devoted to preparing envelopes and kits for the Neighbor-to-Neighbor cancer fund drive. This work was done at the home of Mrs. Grant Hartnagel who is county chairman of the drive. Mrs. E. H. Juers, another Auxiliary member, is chairman of the drive in Red Wing.

The April meeting was held at the Hastings State Hospital, with luncheon at the Hotel Gardiner in Hastings. Dr. William Scheely spoke to the group and conducted a tour of the state hospital.

The May 21 meeting will be held at the Edgewood Cafe in Cannon Falls with a meeting following at the home of Mrs. Marland Williams on Lake Byllesby. Mrs. Corrin Hodgson, of Rochester, will show the film, "South of Sahari."

During June, July and August, the group will hold specially-called meetings only. In September, the meeting will be devoted to public relations, and in October, there will be a speaker on mentally-retarded children. The November meeting will be devoted to legislative matters, and in December, the group will hold its annual dinner meeting with the Goodhue County Medical Society.

St. Louis

Mrs. Earl E. Barrett, president, reports that the St. Louis County Auxiliary has presented a gift of \$250 to AMEF, has given two scholarships to student nurses and two YWCA campships, and has placed *Today's Health* in all of the public schools. "Now, to tell you of our special accomplishment," states Mrs. Barrett.

"As is true of all organizations, some women in past years worked hard and diligently for the Auxiliary and earned money the hard way—rummage sales, luncheons, keno, auctions of articles brought to meetings, and so on. Every dime and quarter counted and was invested. The amount grew and was used from time to time as a loan scholarship for nurses. Times change, however, and this particular type of scholarship was unused for several years.

"This year, we felt it was time to do something constructive with this fund, so we voted to furnish one private room at St. Luke's Hospital in Duluth and

another room at St. Mary's Hospital. Under the able and willing leadership of Mrs. M. A. Nicholson, chairman of the committee, this has been accomplished, and we now have a bronze plaque on each door and can look with pride at what can be done when an organization is as fortunate as we in having hard-working, willing and able members."

Zumbro Valley

The Zumbro Valley Medical Auxiliary, in conjunction with the American Cancer Society, held a meeting on Wednesday, March 13, at the Mayo Foundation House in Rochester. Tea was served followed by a business meeting. A film on "Breast Cancer—Self-Examination" was shown with a talk and discussion led by Dr. Elizabeth Mussey, Rochester obstetrician and gynecologist.

THOUGHTS ON BEING A MEMBER OF THE ADVISORY COMMITTEE

When Auxiliary presidents retire from office
They are commonly called "P.P.'s."
So as not to become a problem
They are given a job of ease.

Page seven in our state handbook finds
Five of us listed there.
You'll see our names and titles,
And a little space to spare.

But nary a word of our duties,
'Though instructions for others you'll see
We're sort of an honorable mention,
From our past that used to be.

But surely there must be a reason
For listing our names in print.
We must have something of value
'Though we have come to the end of our stint.

We are a sort of a vest pocket edition
To be referred to or just ignored,
But will answer your questions gladly
And assure you we won't be bored.

When your duties seem overwhelming,
And you're tired at the end of the day;
When your mind is going in circles,
And you question, "Does Auxiliary work pay?"

It is then you will find us helpful,
For our problems, too, were the same;
So, come and lean on our shoulders,
And you will find we are more than a name.

BY MRS. C. L. SHEEDY, Austin

REHABILITATION IN TUBERCULOSIS

(Continued from Page 334)

for such harder physical labour as packing and polishing. There is no sentiment in business and we do not ask for it; our contracts are obtained in the open market. The work is of the highest quality; there is no better workman than the rehabilitated tuberculous patient.

The settler can leave at any time if he so wishes, but a large number have remained and reared their families for periods of twenty and more years. They make their contribution to the state in income tax; they contribute to the national economy; they do not live on Government subsidies or on charity, although they know we will not see them or their families suffer should they again become ill. They do not suffer the indignity of ostracism, but live in an English Village, with the full rights of citizenship, as self-supporting and self-respecting members of their community. They enjoy, and rightfully, a position which demonstrates one aspect of the true and human end of treatment.

Many others with disability should share their lot; cardiacs, arthritics, paraplegics, psychotics, static poliomyelitis cases and respiratory cripples from non-tuberculous disease. All such of our unfortunate brethren have a right to live and work within their functional ability. "Employment is nature's best physician, and is essential to human happiness."

RICHARD R. TRAIL, M.D.
London, England

TUBERCULOSIS AND OUR STANDARD OF LIVING

The least tangible but probably the most potent factor in the existing favorable trend in mortality from tuberculosis is the general improvement in the standard of living. Greater earning power has made possible more adequate nutrition and better housing. Reduction in the average size of families has reduced overcrowding, which in turn has lessened opportunities for the spread of infection. Where economic levels have continued high, tuberculosis rates have fallen; when war or famine has intervened, they promptly rise. It is more than coincidence that the levels of tuberculosis throughout the world are closely related to the economic level of the populations concerned.—ALTON S. POPE, M.D., and JOHN E. GORDON, M.D., *Am. J. Med. Sciences*, Sept., 1955.

In Memoriam

THOMAS HUNTER DICKSON

Dr. Thomas H. Dickson, formerly Medical Director of the Minnesota Mutual Life Insurance Company with headquarters in Saint Paul, was born March 2, 1884 in Saint Paul and died March 10, 1957.

Dr. Dickson attended Central High School, where he graduated in 1900. He obtained an A.B. degree from Macalester College in 1904 and his M.D. degree from the University of Minnesota medical school in 1910. At the University, he was a member of the Nu Sigma Nu medical fraternity and maintained an active interest in his fraternity in later years. After interning at the City and County Hospital, now known as Ancker Hospital, in 1910-1911, he practiced in Saint Paul until he was appointed Assistant Medical Director of the Minnesota Mutual Life Insurance Company in 1917. In 1924, he became Associate Medical Director and, in 1935, Medical Director, which position he held until his retirement April 1, 1949.

Dr. Dickson was a member of the Association of Life Insurance Medical Directors and twice served as chairman of the medical section of the American Life Convention which is made up of medical directors and assistant medical directors of life insurance companies.

A member of the Macalester Presbyterian Church for many years, he was also one of the earlier members of the Saint Paul Athletic Club and a charter member and past president of the American International Professional Institute.

He was a member of the board of directors of the Saint Paul Y.M.C.A. from 1914 to 1944, treasurer of the organization for ten years, and president from 1939 to 1944, an office at one time held by his father, Thomas H. Dickson, Sr.

He also served as a member of the first Social Planning Committee of the Council of Social Agencies of the Saint Paul Community Chest.

Dr. Dickson was a member of the Ramsey County Medical Society, the Minnesota State Medical Association and American Medical Association from 1911 until he became affiliate member of each organization upon his retirement from active practice in 1949.

Dr. Dickson married Grace L. Vaughan-Rogers on June 22, 1916. He is survived by his widow, who now lives at 18350 Lorne Street, Reseda, California.

Dr. Dickson, "Tom" to his many friends, found his proper niche when he turned his attention to life insurance. He had a special aptitude for vital statistics and even more important, he was friendly in his contacts with people. Above all, he was a fine Christian gentleman.

CARL B. DRAKE, M.D.

CARL ALFRED INGERSON

Dr. Carl A. Ingerson, former Ramsey county coroner, died March 23, 1957. He was seventy-three years old.

He was born in February, 1884. He graduated from Hamline University, the University of Minnesota, and Marquette University, and began his practice in 1910. In 1911, he was appointed police surgeon for Saint Paul. He resigned this post in 1918 when he was elected coroner, a post he held until 1955 when he resigned because of failing health.

Dr. Ingerson was a member of Phi Rho Sigma medical fraternity, a past potentate of Osman Temple of the Shrine, past exalted ruler of the Elks, past governor of Moose Lodge 40, past president of the Minnesota State Order of Moose, a member of numerous Masonic bodies in Minnesota, a life member of the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association. He was also a former vice president of Local 30 of the musicians' union and attended many conventions of the Minnesota State Federation of Labor as a delegate from the Trades and Labor Assembly.

Survivors include his wife, Margaret; one son, Carl A., Jr., and one daughter, Carol, all of Saint Paul.

AUGUST EMANUEL JOHNSON

Dr. August E. Johnson, treasurer and a board member of Swedish Hospital, Minneapolis, died March 21, 1957. He was seventy-four years old.

A Minneapolis resident for more than sixty years, Dr. Johnson was born in Wisconsin and received his medical education at the Minneapolis College of Physicians and Surgeons, from which he graduated in 1903.

Specializing in surgery, Dr. Johnson was a member of the American College of Surgeons, the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association. He also belonged to the Arcana Masonic Lodge 187, Scottish Rite, Zuhrah Temple, the Minneapolis Athletic Club and Phi Rho Sigma fraternity.

Survivors include his wife, Marie; a daughter, Mrs. Guy Howard, Toledo, Ohio; a son, Dr. Robert E. Johnson, Minneapolis, and two sisters, Mrs. Ruth Hall, Tice, Florida, and Mrs. Vera Schindler, Mount Vernon, New York.

ALOYS PETER MAHOWALD

Dr. A. P. Mahowald, a member of the Fergus Falls State Hospital staff for the past five years, died suddenly March 10, 1957, in Fergus Falls. He was sixty-five years old.

Dr. Mahowald was born in Bird Island, Minnesota, attended St. John's University and received his medical education at St. Louis University School of Medicine in St. Louis, Missouri. During World War I he served

**TWO MINNEAPOLIS MEN ORDERED
TO SERVE TERMS FOR ABORTION**

*Re: State of Minnesota vs. William J. Dewars
and Rene Merl Albert*

On March 13, 1957, William J. Dewars, thirty-nine, 2519 East 25th Street, Minneapolis, entered a plea of guilty to an information charging him with the crime of abortion and also to a charge of having a prior conviction for a felony before the Hon. Levi M. Hall, Judge of the District Court of Hennepin County. At that time, Judge Hall sentenced the defendant to serve one year in the Minneapolis Workhouse. Dewars had previously, on March 1, 1951, been convicted in Hennepin County District Court of the crime of forgery in the second degree, at which time he was placed on probation for a period of four years, the first year being served in the Minneapolis Workhouse.

On March 26, 1957, the defendant Rene Merl Albert, twenty-five, 418 21st Avenue South, Minneapolis, was sentenced by the Hon. Michael J. Dillon, Judge of the District Court of Hennepin County, to a term of five years in the State Reformatory for Men at St. Cloud, Minnesota, pursuant to his plea of guilty, which he had previously entered on February 25, 1957, to an information charging him with the crime of abortion.

Before being sentenced by Judge Dillon, Albert also entered a plea of guilty to a charge of having a prior conviction for a felony, the defendant having been convicted of burglary in the third degree on November 21, 1953, at which time he was placed on probation for five years by the Hon. Theodore B. Knudson, Judge of the District Court of Hennepin County. Since Judge Knudson had already revoked Albert's probation on the burglary charge and had ordered him to serve a term of not to exceed five years in the State Reformatory for Men, Judge Dillon ordered that the execution of the defendant's sentence on the abortion charge be stayed and that the defendant be again brought before the Court upon his release from the reformatory for final disposition of the case. According to court records, on April 17, 1950, the defendant Albert had also been convicted in Federal District Court in Seattle, Washington, of the crime of transporting a stolen automobile across a state line, for which he was sentenced to serve eighteen months in the Federal Correctional Institute at Engelwood, Colorado.

Both defendants had been charged with the crime of abortion in a complaint issued by the Hennepin County Attorney's office on February 21, 1957, after a statement given to the authorities by a twenty-year-old Minneapolis divorcee indicated that a "doctor," who was identified as Dewars, had performed an abortion upon her by means of a catheter. Although the patient stated that both Dewars and Albert gave her injections of penicillin, she nevertheless became ill after the illegal operation and was hospitalized for five days in a Minneapolis hospital. The defendant Albert claimed that he paid over to Dewars the entire \$225.00 that was paid by the patient for the abortion. At the time of his arrest Albert was employed by a Minneapolis paint company, but he stated that he had also worked for Dewars as a "bouncer or floor man" in his tavern. Neither of the defendants has any medical training nor does either hold any type of license to practice healing in the State of Minnesota.

**ORDERLY IN MINNEAPOLIS NURSING
HOME SENTENCED FOR VIOLATION
OF DRUG ORDINANCE**

Re: State of Minnesota vs. Eugene Aron

On March 5, 1957, Eugene Aron, twenty-nine, 1416 Xerxes Ave. N., Minneapolis, was sentenced to a term of ninety days in the Minneapolis Workhouse by the Hon. Betty W. Washburn, Judge of Minneapolis Municipal Court, pursuant to his plea of guilty to a charge of having instruments in his possession for the use of narcotic drugs, in violation of the ordinances of the City of Minneapolis relating to narcotic drugs. However, Judge Washburn stayed the execution of the sentence for a period of one year and then warned the defendant that if he should become involved in similar difficulties during this time, he will be compelled to serve his sentence and also an additional ninety day sentence.

Aron, who was employed as an orderly in a Minneapolis nursing home on February 27, 1957, was arrested on March 3, 1957, after the authorities in charge of the nursing home were informed that he had given a hypodermic injection to one of the patients. When the defendant was arrested at his home the following items were found in his possession: two hypodermic needles, one eye dropper adapted to fit the hypodermic needles, one empty capsule and one steel spoon with a residue in its bowl. It was because of his possession of these articles that the defendant was charged with the crime referred to above. According to court records Aron has one previous conviction, having been sentenced on August 16, 1952, by the Hon. Thomas L. Bergin, Judge of Minneapolis Municipal Court, to a term of ninety days in the Minneapolis Workhouse on a charge of vagrancy.

ALOYS PETER MAHOWALD

(Continued from Page 345)

with the U. S. Navy. Following the war, he resided in Albany, Minnesota, where he practiced until he moved to Fergus Falls in 1952.

A member of the Park Region District and County Medical Association, Dr. Mahowald also belonged to the Minnesota State Medical Association and the American Medical Association. He is a former member of the Stearns-Benton County Medical Society. He was a member of the Order of Foresters and the Catholic Aid Association.

He is survived by his wife, Cecelia; three daughters—Mrs. P. W. Quick, Dr. Margaret Mahowald and Mary Mahowald; three sons—Theodore Mahowald, Dr. Mark Mahowald, Anthony Mahowald, S.J., and Paul Mahowald, N.S.J.; one sister—Mrs. George Nistler, Shooks, Minnesota, and three brothers—Msgr. E. Mahowald, Wadena; Anthony Mahowald, St. Cloud, and Herman Mahowald, Duluth.

General Interest

Dr. John F. Briggs, St. Paul, spoke on "Spending the Charity Dollar" at the March workshop of the St. Paul Inter Club Council.

* * *

Dr. Louis A. Buie, Rochester, received a scroll from the National Foundation for Infantile Paralysis recently. The award was made for Dr. Buie's services in the fields of administration and medical affairs for the Foundation.

* * *

Dr. Philip S. Hensch, Rochester, was a member of the Symposium on Rheumatic Diseases held in Stockholm, Sweden, April 14-18. Before his trip abroad, Dr. Hensch delivered the annual Nu Sigma Nu medical fraternity lecture before the student body of the University of Pittsburgh medical school. He also attended recent meetings of the American College of Physicians in Boston.

* * *

Dr. Owen H. Wangenstein and Dr. B. J. Kennedy, Minneapolis, spoke at the section meeting of the American College of Surgeons in St. Paul last month.

* * *

Dr. L. L. Sogge, Windom, was honored by the Windom Good Samaritan Home recently. The home voted to change its name to the "Sogge Memorial Home" in recognition of the many contributions in time and energy made to the project and to the community by Dr. Sogge.

* * *

Dr. Malcolm A. McCannel, Minneapolis, returned recently from nine weeks of practice at the Holland Eye Clinic in Shikarpur, Pakistan. One of the high points of Dr. McCannel's trip was a plane-and-car visit to Tensing Norkay, who is one of the first two men to climb Mount Everest.

* * *

Dr. Kenneth Peterson reopened his medical and surgical practice in Hutchinson, Minn., April 2, after receiving his discharge from the U. S. Army. Dr. Peterson practiced in Hutchinson from 1945 to 1955.

* * *

Dr. Leo G. Rigler, head of the Department of Radiology at the University of Minnesota, has resigned effective June 30 to become consultant of Cedars of Lebanon Hospital in Los Angeles, California. He will also teach, part-time, at the University of California Medical School in Los Angeles.

Dr. Rigler was a member of the Grand Rounds panel on "Pre-Malignant and Malignant Lesions of the Breast and Colon" seen over closed-circuit television at the Leamington Hotel in Minneapolis March 27.

* * *

Dr. Lester L. Bissinger, previously associated with the Brainerd Clinic, opened an independent practice recently. His offices are located in the Parker Building in Brainerd.

Dr. George W. Heine has discontinued the practice of medicine in Little Falls and taken a residency at University Hospitals, Minneapolis.

* * *

Dr. Gordon R. Kamman, of St. Paul, gave the commemorative address at the Seventh Anniversary celebration of the Fergus Falls Mental Hygiene Clinic which was held at Fergus Falls on Tuesday, April 9, 1957. His subject was "The Mental Hygiene Clinic and the Community."

* * *

At the invitation of the surgeon of the Fifth Army in Chicago, Dr. John S. Lundy of the Section of Anesthesiology of the Mayo Clinic spent the month of March visiting midwest and southwest army camp installations. Before returning home he participated in the thirty-first annual congress of the International Anesthesia Research Society in Phoenix, Arizona.

* * *

Dr. John W. Vance, a fellow in internal medicine in the Mayo Foundation and commander of the Medical Flight of the 9709th Air Reserve Squadron of Rochester, has been promoted to the rank of captain in the Air Force Reserve.

* * *

The medical staff of Fairview Hospital, Minneapolis, has elected Dr. Ragnar Soderlind chief of staff to succeed Dr. L. J. Roberts. Dr. Harry B. Hall is chief of staff-elect, Dr. Ralph Silas is secretary, and Dr. Harry O'Phelan is treasurer.

* * *

Drs. Howard Burchell and Jesse Edwards of the Mayo Clinic participated in a conference at Marquette University, Milwaukee, Wisconsin, May 15 to 18 on the subject "Work and the Heart." This conference will consider all the available data on the employment of persons with heart disease, in the hope that further investigation into the effect of employment on damaged hearts will be more effectively directed.

* * *

Dr. K. J. Halverson, a native of Albert Lea and a graduate of the University of Minnesota Medical School, has joined the staff of the Aitkin Clinic. Since his graduation in 1955 he has been practicing in Paynesville.

* * *

A research grant of \$173,117 has been made by the National Advisory Cancer Council to Dr. John J. Bittner, head of the University of Minnesota's department of cancer biology. The grant, which was made through the National Cancer Institute, a division of the U. S. Public Health Service, will enable Dr. Bittner to continue for the next five years his study of cancer in mice. Most of the new grant will be used for salaries for eight or ten assistant research workers, the rest for animal care.

(Continued on Page A-34)

CONFIRMED THERAPEUTIC UTILITY

Pro-Banthine[®]...

A Primary Drug in Peptic Ulcer

Among the many clinical indications for Pro-Banthine (brand of propantheline bromide), peptic ulcer is foremost. During treatment, Pro-Banthine has been shown repeatedly to be a singularly valuable agent when used in conjunction with diet, antacids, sedation and psychotherapy as required. Lichstein and his associates* report that Pro-Banthine "proved almost invariably effective in the relief of ulcer pain, in depressing gastric secretory volume and in inhibiting gastrointestinal motility. The

incidence of side effects was minimal. . . ."

The therapeutic utility and effectiveness of Pro-Banthine in the treatment of peptic ulcer are repeatedly confirmed in the medical literature. Dosage: One tablet with each meal and two tablets at bedtime. G. D. Searle & Co., Chicago 80, Illinois, Research in the Service of Medicine.

*Lichstein, J.; Morehouse, M. G., and Osmon, K. L.: Pro-Banthine in the Treatment of Peptic Ulcer. A Clinical Evaluation with Gastric Secretory, Motility and Gastroscopic Studies. Report of 60 cases, Am. J. M. Sc. 232:156 (Aug.) 1956.

SEARLE

a potent germicide *For Cold Sterilization*

Pheneen®

ELIMINATES DOUBTFUL STERILITY
IN OFFICE USE . . .

Rapid germicidal activity plus specific sporacidal properties enable PHENEEN to provide the extra margin of safety during minor office surgery. Instruments may be stored for months in PHENEEN without weekly changes of solution.

Special "built-in" rust inhibitor makes this possible. Routine use of colorless, odorless PHENEEN reduces questionable sterility to the minimum. For complete information and prices write . . . MM-557b.

Minneapolis 3, Minn.

(Continued from Page 384)

Dr. Edward J. Detjen, Bigfork, escaped injury in late March when his plane landed on the soft ice of Grave Lake north of the Suomi community, when he was responding to an emergency call in that area. The plane was not damaged, but bogged down in soft slush, and Dr. Detjen had to walk more than three miles to make his call.

* * *

Jack W. Rivall, assistant superintendent of St. Luke's Hospital, Duluth, took over his new duties as superintendent of Doctor's Memorial Hospital, on May 1. Mr. Rivall, who is a native of Hibbing, is a graduate of Carleton College and has a master's degree in hospital administration from the University of Minnesota.

* * *

Austin is the new location of Dr. Herman Miller, formerly of Grand Meadow, who has just been released from the U. S. Air Force. He is a graduate of the University of Minnesota Medical School, and while in the air force served as base surgeon at Bossier Base, Shreveport, Louisiana.

* * *

Dr. E. A. Meyerding, executive secretary of the Minnesota Tuberculosis and Health Association for the past thirty-three years, has announced his resignation, effective April, 1958. He gave ill health and his age of seventy-seven as the reasons for resigning. During his tenure with the Tuberculosis Association, he has seen the Minnesota death rate from tuberculosis drop from 69.5 per 100,000 population in 1924 to 4.6 per 100,000 population in 1954. Dr. Meyerding was executive secretary of the Minnesota State Medical Association from 1924 to 1937.

* * *

Dr. D. Morrison Masson, senior consultant in the Section of Internal Medicine at the Mayo Clinic, was honored at a dinner given by his associates at the time of his retirement from the Clinic staff, March 31, after thirty-six years of service.

* * *

Aitkin will have two more doctors within the near future, when Drs. George Pettersen and Richard Burman, both University of Minnesota graduates, arrive June 1 and July 1, respectively, to begin practice. Dr. Pettersen, who is a native of St. Paul, has practiced for four years at Mabel and is completing a year's training in surgery at Bethesda Hospital, St. Paul. Dr. Burman, who is a native of Aitkin, will arrive July 1 upon completion of his internship at Bethesda Hospital.

* * *

Dr. Edgar V. Allen, internist of the Mayo Clinic, professor of medicine in the Mayo Foundation, and president of the American Heart Association, spoke on "The Meaning of Research" before the regional meeting of members of the staffs of heart associations affiliated with the American Heart Association in Omaha, Nebraska, on March 20.

* * *

Two new consultants and five assistants to the staff

of the Mayo Clinic were announced in late March. Named to the staff are **Dr. Howard R. Terry, Jr.**, in anesthesiology, and **Dr. Richard W. Weeks** in general medicine. The newly-appointed assistants to the staff are **Drs. Leonard A. Aaro**, obstetrics and gynecology; **Thomas L. Brannick**, psychiatry; **Homer R. Goehrs**, medicine; **Robert E. Lee**, radiology; and **Robert E. Yoss**, neurology.

* * *

Dr. E. Jane Watson, who has been associated with the Rochester State Hospital since January, 1956, took over her duties as assistant professor in psychiatry at the University of Chicago on April 1. She will work jointly in the departments of child psychiatry and education, and will do teaching and research in connection with the orthogenic school.

* * *

The Greater St. Paul Community Chest and Council at its recent annual meeting paid tribute to **Dr. Robert Rosenthal**, a member of the Public Health Council, and presented him with an award for "outstanding service in planning for human needs."

* * *

Dr. George M. Higgins, who retired from the Mayo Clinic staff in December, 1955, after twenty-four years of service, has returned to Rochester after spending six months in Houston, Texas, where he served on the teaching staffs of the University of Texas and Baylor University. In September he will return to Houston to teach for another seven months. While in Rochester for the summer, Dr. Higgins will continue his affiliation with the executive committee of the Methodist Hospital.

* * *

The American College of Allergists at its thirteenth annual meeting in Chicago, March 14-16, elected **Dr. Giles A. Koelsche** of Rochester as first vice president. Dr. Koelsche is assistant professor of medicine in the Mayo Foundation and consultant to the division of medicine in the Mayo Clinic.

* * *

At a recent meeting of the American Heart Association, **Dr. Joseph F. Borg**, Saint Paul, was elected to membership of the Executive Committee of the Scientific Council of the American Heart Association.

* * *

The American Foundation for Allergic Diseases has appointed **Dr. William Sawyer Eisenstadt**, Minneapolis, as chairman for the state of Minnesota.

* * *

The thirty-third Kober Lecture at Georgetown University, Washington, D. C., was delivered recently by **Dr. Winchell McK. Craig**, head of the Section of Neurosurgery at the Mayo Clinic from 1946 to 1956 and professor of neurosurgery in the Mayo Foundation Graduate School, University of Minnesota. His subject was "The Challenge of Pain Syndromes."

* * *

Approximately 600 physicians attended the Mayo Clinic Clinical Reviews for general practitioners, April 1-3. During the three-day session, thirty-four talks were given on a wide variety of medical subjects designed especially to satisfy the needs of the physician

the choice of doctors . . . WHO DEMAND THE BEST **P&H** TREATMENT TABLE

- Upholstered in Naugahyde covering
- Modern design and sturdy construction
- Legs of 1-inch chrome plated steel tubing

This modern table has been designed especially for P&H. It is modern in trend and sturdy in construction. 72" length accommodates all patients. The legs are made of 1" steel tubing, triple-plated with copper, nickel and chrome. The top is well padded and covered with Naugahyde. Overall dimensions are: 72" long, 26" wide and 30" high. When ordering specify number . . . MM-557a.

Physicians & Hospitals Supply Co.
1400 Harmon Place Minneapolis 3, Minn.

who practices general medicine largely with his own resources. Lectures, discussions, medical motion pictures, and medical exhibits were the instruction media used. Staff members of the Clinic serving as instructors were Drs. Edward A. Banner, Haddon M. Carryer, Edwin D. Bayrd, B. Marden Black, James T. Priestley, Robert L. Parker, J. Arnold Borgen, Clark H. Millikan, Raymond J. Jackman, John R. McDonald, and Herman J. Moersch.

* * *

A former fellow in the Mayo Foundation, Dr. Ralph M. Beddow, has been named acting medical director of Queen's Hospital in Honolulu, Hawaii. Since completing his fellowship in medicine at Rochester, Dr. Beddow has been at Queen's Hospital where he has been head of the outpatient department and chief medical resident.

* * *

On April 8, 1957, Dr. C. J. Watson, head of the University of Minnesota Medical School's department of medicine, delivered the John Phillips memorial lecture before the American College of Physicians in Boston. His subject was "Some Challenging Aspects of Hemoglobin Metabolism."

* * *

In addition to Dr. A. I. Rajala of Grand Rapids, who holds office hours at Floodwood, Minnesota, on Fridays, Dr. R. T. Kelly of the Itasca Clinic is now having Tuesday hours in the Floodwood community.

STATISTICS ON OBSTETRICAL COSTS, HOSPITAL OCCUPANCY

(Continued from Page 340)

cent recommended by the American Hospital Association and the U. S. Public Health Service. Occupancy figures have been averaging well over the 90 per cent mark since January.

CONTRIBUTIONS TO MEDICAL SCHOOLS INCREASE

A recent report shows that contributions in 1956 to the nation's 82 medical schools totaled \$1,862,016 from 1,737 business and industrial organizations, states the chairman of the National Fund for Medical Education.

Seventy-three life insurance companies headed the list with \$313,702; fifty-one pharmaceutical companies were next with \$198,205. Petroleum and natural gas companies were third. Twenty automobile companies gave \$132,900; sixty-seven chemical companies gave \$123,930, and sixty-seven iron and steel companies gave \$120,320.

BLUE CROSS-BLUE SHIELD NEWS

Blue Cross subscribers are utilizing their coverage at an ever-increasing rate. During the first two months of 1957, 203,772.2 days of hospital care were provided for 32,990 participant subscribers compared to 181,708.5 days of care provided for 29,571 participant subscribers during the same period of time of the previous year.

Although some of this increase in Blue Cross activity is attributable to growth in enrollment, the number of cases paid per 1,000 contracts protected increased from 456 per 1,000 contracts to 477 per 1,000 contracts for these periods of comparison. In addition the average length of hospital stay shows a one-tenth of a day increase over the same period of the previous year.

The type of hospital case showing the greatest increase in number is accident cases. During these first two months of 1957, Blue Cross has provided care for 500 more persons per month than during the same period of 1956.

Blue Cross benefits per day averaged \$1.75 higher during January and February 1957 compared to the same period of 1956. Here again these increased benefits can be attributed both to our policy of offering a higher benefit level of contract and also to increases in hospital costs. Hospital charges for Blue Cross subscribers indicate a \$1.11 per day increase for these periods.

* * *

Frequent inquiries from physicians regarding the availability of a Blue Shield contract for themselves and their families indicate that many doctors are not aware of the fact that they can secure either a Plan A or Plan B Blue Shield contract.

The Blue Shield Board of Directors made Blue Shield contracts available to doctors in February of 1956, and many doctors now have either Plan A or Plan B group contracts. Prior to this action by the Board of Directors, offering Blue Shield contracts to doctors was considered unnecessary because of the courtesy care of a physician and his family by another doctor. However, it was found that many doctors considered Blue Shield coverage a method of solving some of the embarrassments arising from the courtesy care of one physician by another, and it was also learned that most other Blue Shield Plans offer contracts to doctors.

A doctor who wishes to obtain a Blue Shield contract can do so in clinic or doctor's office personnel group, a hospital staff group, or the general medical profession group. If enrollment is not open to him through a clinic, a doctor's office personnel group, or a hospital staff group, an application blank can be obtained by writing to Blue Shield, 2610 University Avenue, Saint Paul 14, Minnesota.

ANNOUNCING

**A Completely New and Timely Addition
to the Year Book Series**

The Year Book Of
CANCER

Edited by RANDOLPH LEE CLARK, JR., M.D., and RUSSELL W. CUMLEY, PH.D., *University of Texas M. D. Anderson Hospital and Tumor Institute*. With the assistance of an editorial board of 27 and 93 consulting editor-authorities.

The Year Book of Cancer brings together under one cover, and for the first time in any language, detailed abstracts (with illustrations and editorial comments) of the best international journal articles on all aspects of the cancer problem. Presented in the concise, terse style for which the Year Book Series is so widely used and appreciated, the truly significant work in research and clinical management now becomes available in a compact, convenient quick-reference format never before obtainable. Ready June. Approx. 475 pages, 190 illustrations. \$7.50.

FIELDS & SEED'S
Clinical Use of RADIOISOTOPES

Just Ready—A simplified, working manual—not a tome intended exclusively for those with specialized interests.

Principal emphasis is on established applications of isotopes in diagnosis and treatment—Thyroid Evaluation, Treatment of Toxic Goiter, Therapy of Blood Diseases, Cancer and Cardiac Therapy, etc.

Additional discussions deal with the radioisotope laboratory, materials, apparatus, radiation safety, glossary of terms, signs, symbols, etc.

By 17 Authorities. Edited by Theodore Fields, M.S., Assistant Director Radioisotope Laboratory, VA Hospital, Hines, Illinois, and Lindon Seed, M.D., Clinical Associate Professor of Surgery, College of Medicine, University of Illinois. 384 pages; illustrated. \$9.50.

THE YEAR BOOK PUBLISHERS, INC.
200 E. Illinois St., Chicago 11, Ill.

Everybody's Going To Europe . . .

YOU Should Go Round The WORLD!

No, there's nothing fantastic about the idea. You probably need a good vacation—one that will really make you forget the cares of your daily practice. A trip to Europe would be great! But we suggest something even better—the vacation you've always wanted—a wonderful trip **Round the World!**

You'll visit Hawaii, Tokyo, Hongkong, Bangkok, Delhi, Calcutta, Damascus, Cairo, Athens—plus, of course, Rome, Paris, London and all the rest! And you won't have to travel by a slow tramp steamer—instead, you'll FLY!

The cost? Not much more than a trip to Europe. Only \$1995 for 38 glorious days of discovering the most thrilling cities in the world!

FREE HOME CONSULTANT SERVICE

You're a busy man, and planning a trip takes time. To save your valuable daytime hours, one of our experienced tour consultants will work out details of your trip, answer questions for you and your wife, in the privacy of your home—whatever evening you prefer. You will be under no obligation.

Call or write Mr. Egan for free information on Round the World or European travel.

Book Reviews

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

DISEASES OF THE NOSE, THROAT AND EAR.

Tenth Edition. Howard Charles Ballenger, M.D., F.A.C.S. Professor Emeritus of Department of Otolaryngology, Northwestern University Medical School, Chicago; Surgeon, Department of Otolaryngology, Evanston Hospital, Evanston, Illinois; and John Jacob Ballenger, B.S., M.S., M.D. Associate in the Department of Otolaryngology, Northwestern University Medical School, Chicago; Associate Surgeon, Department of Otolaryngology, Evanston Hospital, Evanston, Illinois. 968 pages. Illus. Price \$17.50, cloth. Philadelphia: Lea & Febiger, 1957.

EXPECTANT MOTHERHOOD.

Third Edition. Nicholson J. Eastman, M.D. Professor of Obstetrics in Johns Hopkins University; and Obstetrician-in-Chief to the Johns Hopkins Hospital. 198 pages. Illus. Price \$1.75, cloth. Boston: Little, Brown & Co., 1958.

THE RIDDLE OF STUTTERING.

C. S. Bluemel, M.D. Fellow of the American College of Physicians; Fellow of the American Psychiatric Association; Fellow of the American Speech and Hearing Association. 142 pages. Illus. Price \$3.50, cloth; \$1.50, paper cover. Danville, Illinois: Interstate Publishing Co., 1957.

MANUAL OF RADIATION THERAPY.

K. Wilhelm Stenstrom, Ph.D. Professor of Biophysics; Director, Section of Radiation Therapy, University of Minnesota Medical School. Collected by John B. Coleman, M.D., Clinical Instructor in Radiology. Revised with additions and Discussions by Paul C. Olfelt, M.D., Clinical Instructor in Radiology, and Frances Conklin, M.D. 94 pages. Illus. Price \$4.50, cloth. Springfield, Illinois: Charles C Thomas, 1957.

MEDICAL SERVICES FOR RURAL AREAS.

The Tennessee Medical Foundation. Willman A. Massie, Chairman, Health Committee, Council of the Southern Mountains. Formerly Field Secretary, The Tennessee Medical Foundation. 68 pages. Illus. Price \$1.25, paper cover. Cambridge, Massachusetts: Harvard University Press, 1957.

FIGHT FOR FLUORIDATION.

Donald R. McNeil. Associate Director of Wisconsin State Historical Association. 241 pages. Price \$5.00, cloth. New York: Oxford University Press, 1957.

CLINICAL ROENTGENOLOGY.

The Digestive Tract, the Gall Bladder, Liver and Pancreas, the Excretory Tract and Special Studies Emphasizing Differential Considerations. Volume 4. By Alfred A. de Lorimier, M.D., Henry G. Moehring, M.D., and John R. Hannan, M.D. 676 pages. 1112 illus. Price \$24.50. Springfield, Illinois: Charles C Thomas, 1956.

THE PHYSICIAN-WRITER'S BOOK. Richard M. Hewitt, M.D., Section of Publications, Mayo Clinic, Rochester, Minnesota; Associate Professor of Medical Literature, Mayo Foundation Graduate School, University of Minnesota. 388 pages. Philadelphia: W. B. Saunders Company, 1957.

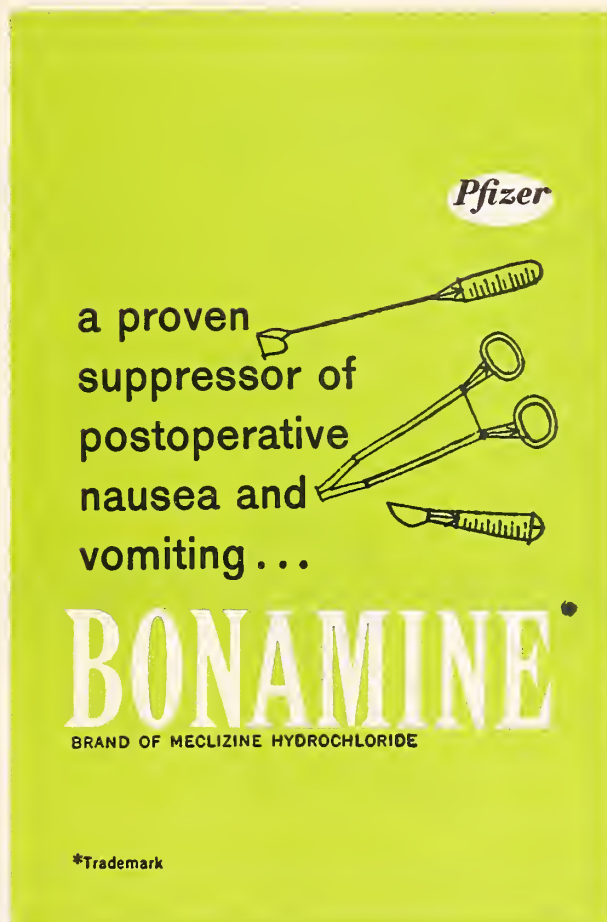

This volume is concerned with "tricks of the trade of medical writing," and is intended to be used by any physician who contemplates submitting papers to medical journals or publishers, or any physician who would like to do so but is unsure of his competence in the writing of medical papers.

The avoidance of "road blocks" to swift communication of ideas, the over-all plan of organization of a composition, common grammatical errors, the "what, when and how" of medical writing are a few of the considerations which the volume develops and explains extensively. The types of writing exemplified in parts of the book range from the basic fundamentals which are absolute requisites to the beginner to the subtle devices which mark the superlative writing of the master authors.

Two examples presented by Dr. Hewitt are taken from the Rochester *Post-Bulletin*. One, from the *Post-Bulletin* of September 14, 1951, concerns a condemnation by the late Associate Justice Theodore Christianson, of the Minnesota Supreme Court, of the "and/or" construction by legal and other writers, on the grounds of doubtful meaning and confusion. The second example is from the *Post-Bulletin* of November 27, 1950, and sets forth the reasons why the word "flammable" is preferable to "inflammable."

The "Physician-Writer's Book" reflects Dr. Hewitt's career in medical writing and medical literature. A graduate cum laude of Wesleyan University in Middletown, Connecticut, he took a master's degree in English at Princeton University before he began to study medicine, and for two years he was also an English teacher in the Sanford School at Redding Ridge, Connecticut. After service in the Army Medical Department in World War I he entered the George Washington University Medical School in Washington, D. C. from which he received the degree of doctor of medicine in 1924. In 1924 and 1925 he served an internship at the Gorgas Hospital in the Canal Zone, Panama, and from 1925 to 1928 he was assistant editor of the *Journal of the American Medical Association* in Chicago.

Dr. Hewitt came to Rochester in 1928 as associate medical editor in the Section of Publications of the Mayo Clinic. He became head of the section in 1933, and became a senior consultant in 1949. During World War II he did editorial work as a member of the Committee on Information, Division of Medical Sciences, National Research Council, as well as similar work for the Office of the Surgeon General of the Army and for the War Manpower Commission. In 1956 he was elected president of the American Medical Writers' Association. He has lectured and written extensively on medical writing and publishing.

The Management of Nodular Goiter

OLIVER H. BEAHRS, M.D.
Rochester, Minnesota

ANY THYROID gland that on clinical examination contains a tumor or tumors, presents an irregular outline, and is asymmetric might be considered to be a nodular goiter. The pathologic processes responsible for these findings include fetal and involutional adenomas, various forms of thyroiditis and carcinoma.

The management of nodular goiter is a controversial subject. The argument revolves mainly around two points, namely (1) whether the incidence of thyroidal carcinoma associated with nodular goiter and the potential hazard of this condition are sufficiently great to justify treatment for an asymptomatic nodular goiter, and (2) the extent of the surgical procedure when a nodular goiter is found to be malignant.

Surgical Versus Nonsurgical Treatment

Support can be found in the current literature for radical surgical treatment^{1,2} of malignant tumors of the thyroid as well as for the opposite view of no treatment at all.³⁻⁵ It is difficult to evaluate statistics regarding nodular goiter and cancer, since the background and approach to the problem are not the same in each study. Factors related to the selection of patients are present whether or not such factors are admitted. Such selection results from clinical suspicion as to the type of goiter present, the limitation of the number of hospital beds, whether the patient is being seen privately or in a teaching or charity practice, the economic status of the patient and the philosophic approach of the physician. The statistics from a series of cases of goiter from a metropolitan charity institution are weighted by symptomatic goiters or those in which the suspicion of

cancer is great, while data from private practice or clinics are more likely to be diluted by asymptomatic goiters, most of which are removed for prophylaxis. The philosophy regarding the management of nodular goiter emanating from an individual institution is based on the experience of the physicians practicing in that institution. The type of patient, the location of the practice and the safety of the surgical techniques, as well as the dangers of the disease being treated, are all taken into consideration. Prophylactic surgical intervention is justified only if the risk of the disease, if left untreated, is greater than the risk of the treatment, including consideration of the practicability of the treatment and the economics involved.

The incidence of nodular goiter in the general population is not known. The estimate that 10 to 15 per cent of adults have nodular goiters that can be detected clinically probably is fairly accurate. However, Mortensen and associates⁶ found that 525 of the thyroid glands in 1,000 consecutive necropsies contained grossly evident nodules. This might indicate that as many as 50 per cent of people have pathologic nodules in the thyroid gland. Of course, the removal of millions of goiters on prophylactic grounds would be entirely impracticable, especially since the risk of subsequent complications as the result of retaining these goiters is not great.

Factors in Selection of Treatment

Some potential hazards must be considered in making a decision as to the management of these lesions. These hazards include the chance of subsequent development of hyperthyroidism, the risk of malignant changes in the thyroid and the possibility of mechanical pressure on structures of the neck. Another factor is the cosmetic appearance of the goiter. Too frequently, only one of these factors is considered in the management of nodu-

lar goiter. Actually, all of them should be weighed in making the final decision as to what recommendation to give the patient.

Hyperthyroidism.—A definite figure cannot be given for the number of patients with adenomatous goiter who eventually will have hyperthyroidism. Most physicians have seen patients in the later years of life who have fibrillation, cardiac decompensation and other evidences of adenomatous goiter with hyperthyroidism. Review of the histories of such patients often discloses that a goiter has been known to have been present for as long as twenty years or more. When the goiter was first recognized, it could have been removed with minimal risk but now the patient is older and seriously ill; thyroidectomy now imposes a considerably increased risk to the life of the patient. It has been variously estimated that hyperthyroidism will develop in 30 to 50 per cent of patients who have adenomatous goiters and who are left untreated. The actual figure probably is considerably smaller but still large enough to be of real significance in any decision concerning the management of patients with nodular goiter.

Carcinoma.—Considerable controversy revolves around the incidence of carcinoma in nodular goiter. The unresolved questions are: 1. Does the chance of the occasional discovery of carcinoma warrant prophylactic thyroidectomy? 2. Does carcinoma of the thyroid warrant surgical treatment?

In a review made in 1951 of a series of 342 cases at the Mayo Clinic in which a clinical or pathologic diagnosis of malignant disease of the thyroid gland was made, it was found that the condition was inoperable in 35 per cent of these cases.⁷ This is a shockingly large incidence when it is realized that the majority of these patients could have been treated adequately if seen earlier.

For many years at the clinic, the incidence of carcinoma of the thyroid gland in surgically removed nodular goiters has been 4 to 5 per cent.^{8,9} This figure is comparable with data reported by other investigators. It is not of clinical significance, however, in that it includes nodular goiters in which the presence of carcinoma was known or suspected before operation and also those in which carcinoma was found incidentally at the time of prophylactic thyroidectomy. A goiter that is known or thought to be malignant will, of course, be

treated. The figure that is of interest in the management of nodular goiter is the frequency with which carcinoma occurs in nodular goiters that are asymptomatic and not suspected of containing carcinoma. My associates and I⁸ have found this figure to be 3.8 per cent. We also found carcinoma in 1 per cent of surgically removed adenomatous goiters associated with hyperthyroidism. As already noted in the aforementioned study of Mortensen's group, 525 of 1,000 thyroids examined at routine necropsy contained single or multiple nodules; primary carcinoma was found in twenty-eight of these glands, an incidence of 5.3 per cent. Metastatic lesions in the thyroid gland from other sources were noted in eighteen other cases. My colleagues and I consider that these figures are sufficiently high to warrant thyroidectomy for most patients who have nodular goiter.

It is difficult to establish accurately on clinical grounds whether or not a goiter contains a single nodule or multiple nodules. When only a single nodule is thought clinically to be present, the pathologist frequently finds multiple nodules when he examines the surgical specimen. Because of this difficulty, we have not made a clinical separation of our cases of nodular goiter into those with single nodules and those with multiple nodules. However, it is reasonable to assume that the chance of malignancy is greater if a discrete palpable nodule is separate from the thyroid gland or from other nodules. Reports of series of such discrete single nodules have indicated that the incidence of carcinoma among these might be as much as 20 per cent.¹⁰

The incidence of carcinoma in nodular goiter is considerably greater in children than it is in adults. Hayles and associates¹¹ found approximately a 50 per cent incidence of carcinoma in nodular goiter in a group of children less than 15 years of age studied at the clinic. Because of this great incidence, any nodule in the thyroid gland of a child should be considered carcinoma until proved otherwise.

Malignant thyroidal tumors may be grouped into two categories, namely (1) the highly anaplastic lesion, for which little can be offered in the way of surgical treatment, and (2) the slowly growing papillary and follicular lesions. The latter group is of more surgical importance; 60 to 70 per cent of carcinomas of the thyroid fall into this category.^{7,8}

Papillary lesions are extremely slow in growth and frequently spread into the tracheo-esophageal and cervical groups of lymph nodes. Opinions regarding the management of these tumors vary from total thyroidectomy and radical dissection of the neck to no surgical treatment at all. My associates and I take a middle-of-the-road position and consider that the results justify this position. Removal of primary thyroidal carcinoma by total lobectomy on the side of the lesion and subtotal lobectomy on the opposite side constitutes adequate treatment of these lesions unless the trachea or esophagus is involved. Radical dissection of the neck is considered advisable only when massive involvement of the cervical lymph nodes is present. If no nodes are felt clinically or at the time of operation, the surgical procedure is not extended into the lateral aspects of the neck. If one node or a group of nodes is involved, then a modified dissection of the neck is done, with removal of only the involved and adjacent tissue. In a review of 174 cases of papillary carcinoma of the thyroid gland with follow-up periods of five to fifteen years, it was found that in no instance had we lost control of the lesion in the lateral aspects of the neck by inadequate surgical intervention in this region.

We do not agree with those who are of the opinion that carcinoma of the thyroid does not require surgical treatment. These lesions will kill the patient if they are left alone. We do not perform needle biopsy of the tumor in the thyroid gland because we consider that inadequate tissue frequently is obtained and that there is risk of seeding carcinomatous cells into the tissues. We prefer to expose the nodule and perform an adequate resection for diagnosis.

Pressure.—In this modern era, physicians see few large goiters causing significant pressure on or distortion of the trachea. However, there is always the occasional case in which the airway is compromised by a large goiter or by one impinging on the thoracic inlet. Progressive obstruction of the airway is most dramatic and requires emergency measures if disastrous results are to be prevented. This hazard also must be considered in the management of patients with nodular goiter. Unfortunately, some patients neglect to seek medical advice until treatment is urgent and has to be carried out at an increased risk to the patient.

Prognosis and Complications in Thyroidal Surgery

The present-day risk of competent thyroidal surgery is extremely low. For asymptomatic nodular goiter, it should approach zero. The over-all mortality rate in 8,972 cases in which thyroidal operations were done at the clinic from 1946 to 1955, inclusive, was 0.1 per cent.¹² Only one death occurred in 4,919 thyroidectomies in patients who had adenomatous goiter without hyperthyroidism. The patient who died was a seventy-four-year-old woman who had a large goiter causing tracheal compression; the goiter was removed satisfactorily but the patient died from a cerebrovascular accident during the postoperative course.

The morbidity associated with prophylactic thyroidal surgery is minimal. Only one instance of permanent postoperative tetany occurred in 566 patients operated on at the clinic in 1954 for adenomatous goiter without hyperthyroidism.¹² The incidence of paralysis of a vocal cord in the same group of patients was less than 1 per cent. Myxedema is an uncommon complication in patients who are operated on for adenomatous goiter. However, myxedema occurs postoperatively in 30 to 50 per cent of patients who have thyroiditis. The incidence of myxedema also is high in patients with thyroiditis who are not treated surgically. Postoperative hemorrhage is a problem on extremely rare occasions. The vast majority of patients undergo thyroidal surgery satisfactorily and have a rapid and complete recovery.

Nonsurgical Treatment

A small number of nodular goiters can be treated by nonsurgical methods. The nodular goiter of lymphocytic thyroiditis, diagnosed on clinical grounds or by needle or surgical biopsy, often decreases in size or disappears when the patient is given adequate amounts of desiccated thyroid. A few patients who have adenomatous goiter with hyperthyroidism are treated by means of radioactive iodine. As information regarding the uptake of radioiodine by thyroidal nodules increases, more adenomas probably will become amenable to such therapy. At the present time, however, surgical intervention should be considered the treatment of choice for the great majority of symptomatic and asymptomatic nodular goiters.

(Continued on Page 406)

Injuries of the Genito-Urinary System

GEORGE L. GARSKE, M.D., F.A.C.S.

Minneapolis, Minnesota

WAR INJURIES, we all hope, will not concern us in the near future; however, if such should occur, the scope of this presentation on genito-urinary injuries will apply. Those injuries seen by us now are the result of modes of transportation, industrial accidents, and the various incidents involving a slip or fall, or a stabbing or gunshot wound. The surgeon, himself, is not immune to producing trauma to the urinary system and neither is the urologist. The laboring and parturient female may encounter sufficient trauma to produce minimal to serious damage to the urinary tract. Irradiation must also be considered as a factor in injury. Injuries are not frequent to the urinary system, but with increased horsepower, increased production, and the means to achieve such, and with more radical surgical methods at hand, one may expect an increase in the future.

Nonpenetrating injuries are seen more commonly than the penetrating variety, and it must be remembered that the distended or abnormal organ is more susceptible and more likely to be injured than the lax or normal one.

Injuries to other body structures, and hemorrhage, with or without shock, are usually associated with urinary tract damage, and may require the emphasis of initial effort of care. A high index of suspicion will make an early diagnosis, and prompt treatment of the urologic problem is then mandatory in preventing or reducing late complications and saving life. Fine judgment is required for the proper timing of diagnostic studies and the correct therapy for the findings of such studies.

Injuries of the Kidney

Injuries to the kidney vary from mild contusions to complete maceration of the entire renal parenchyma, and it is amazing that such a vascular, friable, and mobile organ suspended in fat is not injured more frequently. The majority of injuries occur to the male because of greater vocational exposure, more strenuous physical activity, and the less flexible muscular fixation of the kid-

ney. The kidneys are positioned partially in the thoracic cage shielded by the ribs, the lumbar spine, and the vertebral and abdominal muscles, and are protected anatomically from most ordinary or moderate injuries. Trauma of sufficient force to fracture ribs may force fragments of bone into the kidney substance, or the kidney may be pressed against the vertebral column. The normal mobility of the kidney aids in preventing the full impact of trauma upon it.

Injuries to the kidney are either open or penetrating. In peacetime, the majority of renal injuries are the closed type from transportation, or industrial accidents, athletic activities, or other severe direct force over the renal region. Many of these injuries are slight, causing some pain and hematuria and requiring only expectant treatment. Many civilian accidents, like those with wartime trauma, are so completely devastating that death occurs before focus is brought to possible renal damage. Injury by fall, even of short distance, on the feet, buttocks, or shoulders, may cause indirect renal damage by the mechanism of sudden snap, stop, and flexion, on a downward moving kidney. Instances have been reported where the renal pedicle has been completely torn from the central vascular supply of the body. Renal injuries due to penetrating wounds are rare in peacetime, and are frequently overlooked because of serious and more pressing injuries of adjacent viscera. The urologist may injure the kidney parenchyma, renal pelvis or ureter, during cystoscopic manipulations, particularly with stiff or stiff ureteral catheters, stone baskets, or with overdilatation of the renal pelvis with constant material during pyelography.

Continued advances in urologic diagnosis, use of new therapeutic agents, abundant blood transfusions, more conservative and better timed surgical procedures based on keen judgment have all reduced the initial gravity and late complications of renal trauma.

Closed injuries of the kidney range from minute

subcapsular hemorrhage to total disruption of the parenchyma, with or without injury to the pelvis and vascular pedicle. Perirenal trauma may occur without damage to the kidney or its capsule

usually seen, providing the ureter or pelvis is not obstructed by clot, or a reflux anuria has not occurred. The renal capsule is a most resistant membrane remaining intact following even mod-

Fig. 8. (*lower right*) Rupture of kidney parenchyma and renal pelvis with intraperitoneal extravasation.

and usually presents bleeding with consequent pain and regional enlargement, but seldom with changes in the urine itself. The hemorrhage usually absorbs and does not require open surgical care, but may complicate itself in perirenal hematoma or perinephritis.

Simple contusions of the kidney (Fig. 1) with few to many subcapsular superficial tears of the parenchyma occur frequently. This injury causes brief transient hematuria and some renal pain, and requires no surgical intervention, only observation. The excretory urogram is normal.

With rupture of the parenchyma, perirenal hemorrhage may be marked and hematuria is

erate trauma. The capsule will contain diagnostic radiopaque solution within the renal outline, but with rupture of the capsule the contrast media will extravasate to the perirenal area (Figs. 2, 3, and 4). If the capsule is not torn (Fig. 5), mild to moderate subcapsular hemorrhage is present, but with parenchymal tears involving the capsule, hemorrhage is more severe and may be quickly fatal. One or both poles may be torn from the kidney, usually in a transverse plane, opening the larger arcuate and interlobular vessels. Rarely will urine be found in the wound, unless the tear extends into the pelvis or calyces, for lacerated renal tissue is not usually capable of secreting

urine. It is well to remember that spontaneous rupture occurs in hydronephrotic or pyonephrotic kidneys, and a diseased kidney may be damaged by only minimal trauma.

The completely perforating injury is the most common penetrating wound of the renal parenchyma and the wounds may be slight, especially those in which the edges or renal poles are damaged, but complete destruction of either pole or extensive shattering of the kidney (Fig. 6) may also occur as seen in the closed type lesion. When the central portion of the kidney is injured, the damage is severe and terminates in nephrectomy.

In hilar wounds (Fig. 7), the renal artery or one of its branches may be divided, and the patient usually dies before the diagnosis can be made and treatment by nephrectomy given. Small veins have been known to anastomose after injury, but renal arteries do not; consequently, division of the small arteries causes extensive cortical necrosis. A missile will rarely injure the kidney or its accompanying structures without passing through the abdomen or chest cavity, and the need for immediate surgery of these extrarenal organs is of greater emergency than the care of the kidney itself. Hematuria, pain, and abdominal rigidity of varying degree are present in most instances. Abdominal relaxation sufficient to permit accurate palpation of the renal region does not occur, but occasionally an easily felt large mass in the flank is found, indicating perirenal bleeding. Hemorrhage is the most serious problem in the hilar wounds, and may cease spontaneously by increased pressure in the restricted perirenal space. Urinary extravasation is not marked unless there are extensive pelvic or ureteral tears. Associated rupture of the peritoneum (Fig. 8) allows blood and urine to drain from the closed lumbar space into the peritoneal cavity, and thorough cleansing of the peritoneal cavity must be accomplished at the time of surgery. Intraperitoneal rupture may be rapidly fatal, especially if urinary infection is present.

In all renal injuries, microscopic to massive hemorrhage is present but may not occur immediately. Red cells may disappear for several days after injury, and then recur spontaneously or after exertion. The absence of hematuria may be due to division of the ureter of the damaged kidney, to obstruction of it by clots or fragments of renal tissue, or to extensive damage to the renal pelvis

itself. Customarily, shock is present, and shock developing several days after the initial injury indicates recurrent or increased bleeding. Where injury to the thorax, abdominal viscera, or spinal cord is associated, severe shock is usually present. In the uncomplicated renal injury, the severity of the shock should not be used as an index of the extent of renal damage.

The diagnosis is made on history of injury with subsequent pain in the injured side, mass in the lumbar area, and microscopic or gross blood in the urine. In all instances of abdominal injury, even though no evidence of renal trauma is present, catheterization should be done, if necessary in the male, and always in the female to obtain a specimen for analysis. Pyuria on the initial specimen suggests previous renal disease, but is commonly present several days after injury. A KUB film, portable if necessary, should be done in the presence of extensive secondary injuries which prohibit more detailed urologic studies. Haziness of the renal outline, obliteration or distortion of the margins of the psoas muscle, and/or deviation of the spine away from the involved side, suggests hemorrhage in the perirenal area (Fig. 9). Enlargement of the kidney shadow itself suggests a subcapsular hematoma. Fractures of the vertebrae or bony pelvis may also be seen on this initial film. Excretory urography provides fairly definite information, and more extensive diagnostic procedures may be avoided if this series of films is conclusive. In addition, the possibility of a solitary kidney should be considered, and the excretory study will define the presence and the function of the contralateral kidney. Lack of renal blood flow and consequent decrease in the secretory power of the kidney is present in shock, and the excretory study may be totally nondiagnostic. The injured kidney functions when the renal tissue and its blood supply are intact, but during the period of recovery the secretory and absorptive action of the damaged kidney and the contralateral kidney is inferior to the immediate post-traumatic ability to function. Therefore, excretory urography should be done early to gain the most reliable information. Cystoscopic study, with occlusion ureteral-pyelography with an acorn type catheter may be necessary to establish the correct diagnosis, and will very definitely illustrate ureteral injury. Cystoscopy is hazardous in the shock state or with extensive body injuries, and recurrence of bleeding may follow

instrumental manipulation or moving the patient for the procedure. The risk of infection from cystoscopy and pyelography is minimal, and should be disregarded when an attempt at a definite diagnosis is being made.

lumbar incision should be made which will permit evacuation of clots, visualization of the kidney, adequate drainage of the involved area, and the surgical procedure of choice. The lower angle of the incision can then be extended transversely,

Fig. 9. KUB film demonstrating haziness of renal outline, obliteration of psoas muscle, and deviation of spine away from the involved side.

Fig. 10. Ureterogram of ureter injured by crushing with forceps at time of hysterectomy.

In general, treatment of renal trauma is less urgent than that of complicating lesions, but the important decision is whether exploration of the renal region is required, and, if so, when. Some urologists feel a history of renal trauma with hematuria for a twenty-four-hour duration indicates need of exploration, and others favor cautious delay. Judicious delay allows the patient time to recover from shock, and during this period some of the diagnostic procedures can be carried out. If exploration is finally necessary, surgical hemorrhage is usually less in amount than it would have been immediately after injury. Persistent hematuria, signs of infection, shock or internal hemorrhage, all indicate extensive damage, and exploration is mandatory. Hematuria may not be sufficient reason for early exploration, for primary hematuria many times will cease twenty-four to forty-eight hours after injury, but if it persists and is profuse the kidney should be explored. Urinary extravasation requires prompt and extensive drainage of the area. If exploration is warranted, an adequate

the peritoneum opened, permitting examination of the abdominal viscera and any required abdominal surgery. In primary transperitoneal exploration with probable renal damage, exploration of the renal region by this approach is not advisable for it opens a poorly drained field, readily contaminated by intestinal spillage. If laparotomy indicates exploration of the renal fossa is necessary, a second incision should be made using the lumbar approach, or, if this is not feasible at the time, a generous stab wound can be made in the lumbar area and drained with a large caliber, many-holed catheter or a number of Penrose drains, until the patient's condition stabilizes from the transperitoneal procedure.

The usual surgical procedures for trauma of the kidney are: (1) drainage of the renal region, (2) partial nephrectomy or repair of the injured kidney, or (3) nephrectomy. Drainage is the most satisfactory procedure when shock is present or exploration urgent, for it permits inspection, evacuation of blood clots, and control of hemorrhage

quickly with only minimal risk to the patient. Foreign bodies and loose tissue fragments should be searched for and carefully removed at the time. Drains, including nephrostomy, should be placed

Fig. 11. Sites of ureteral injuries and methods of repair.

freely, but carefully, to reach all parts of the wound. Partial nephrectomy, renal repair, and reconstructive operations, can be considered for closed, uninfected, renal rupture, but are fraught with complications for infected penetrating wounds. In marked destruction of renal parenchyma, extensive reconstructive surgery usually results in a poorly functioning or functionless kidney with eventual nephrectomy. With partial nephrectomy, or suture, parenchymal infections, necrosis, and late bleeding may necessitate secondary nephrectomy. The kidney must be removed in cases of constant hematuria, multiple deep lacerations of the parenchyma, or damage to the vascular pedicle. If the ureter is severed, the pelvis torn, and the kidney severely lacerated and with urine escaping from the wound, late results are a nonfunctioning or persistently infected kidney. Nephrectomy is a simpler procedure than most conservative or repair operations, and usually is the final result anyway at a later operation, if primary repair is attempted.

A general outline for control of renal trauma is as follows:

1. Accurate history and careful examination.
2. Complete blood count, hematocrit, and urinalysis with urine culture and sensitivity studies.

3. Immediate treatment of shock with plasma until blood is available.
4. Excretory urography when systolic pressure reaches 90 mm.

8. Generous use of antibiotics.
9. Excretory series frequently in postoperative period.

Injuries of the Ureter

The course of the ureter is remarkably well protected from accidental trauma and injury from external violence, except from the rare penetrating wound. Conversely, various means of intra-ureteral manipulation through the cystoscope, and extensive pelvic surgery constitute a tragic, not infrequent, source of ureteral injury. Ureteral injuries from external trauma are frequently overlooked, for the usually critical accompanying visceral injuries preclude early recognition of the lesion, and the severity of abdominal symptoms or fractures may entirely mask the evidence of ureteral injury. External penetrating injuries involving the ureter are confined to gunshot and stab

wounds; however they have been reported with fractures of transverse processes of the lumbar vertebrae.

Accidental surgical ureteral injury occurs during right colectomy, combined abdominal-perineal resection and with both simple and radical gynecologic operations. The injury may vary from excision of a sizable segment of ureter to minimal clamping, crushing, or ligation (Fig. 10). Most ureteral injuries are not suspected at the time of initial surgery and are recognized in the immediate or late post-operative period by a urinary extravasation, pain, sepsis, anuria, or fistula formation.

Attention is first directed to the control of shock, after which the manner of treating the ureteral injury depends upon the location, the extent of injury, and the time the lesion is discovered, after the original trauma (Fig. 11). When shock has been completely controlled, excretory urography and subsequent cystoscopic study with occlusion ureteral-pyelography must be done. The pelvic portion of the ureter is more frequently injured in penetrating wounds for in this location the ureter is fixed, relatively inelastic, and poorly protected by other structures. Damage to the vascular supply to the lower extremities may be so great that the diagnosis of severed ureter is made at autopsy. Extravasation of urine from ureteral injury, without drainage, is much less severe than extravasation from the bladder or urethra. When the ureter has been injured and tissues have obliterated the path of the bullet or other missile, extravasation of urine forms a mass in the adjacent area with sepsis, and usually results in fistula formation, which is the late characteristic sign of an unrecognized ureteral injury.

If injury is suspected, an immediate excretory urographic series should be made, not only to determine the possible site of the injury but to determine the function of the contralateral kidney. This should be followed by cystoscopic study with occlusion ureterography with an acorn type ureteral catheter impacted in the ureteral orifice of the injured side (Fig. 12). An attempt should be made to pass an indwelling ureteral catheter, and even though this does not reach the renal pelvis and is passed only to the site of obstruction it should be left indwelling and immediate exploration carried out. Only rarely is bilateral ureteral ligation seen, and this usually follows an extremely difficult vaginal hysterectomy, or occasionally a cystocele repair.

If the diagnosis of injured ureter is made at the time of the initial operative procedure, an indwelling ureteral catheter should be passed as a splint and left indwelling for seven to ten days after

Fig. 13. Repair of mid-ureteral injury with a diverting ureterostomy by indwelling ureteral catheter placed to the renal pelvis and an indwelling ureteral catheter placed proximal to the site of injury and anastomosis.

anastomosis at the site of injury has been completed and a diverting ureterostomy established. In injury of the upper third of the ureter a direct anastomosis may be completed if the injury is early; however, at a later stage preliminary nephrostomy may be necessary, followed by an attempt at direct anastomosis. If anastomosis is unsuccessful, nephrectomy is inevitable. In mid-ureteral injury (Fig. 13), direct anastomosis over a splinting catheter with a diverting ureterostomy is done if the injury is immediately recognized. However, if the injury is seen late, nephrostomy, preliminary to definitive corrective procedure, is indicated. In the injuries of the lower third of the ureter, primary anastomosis is carried out if the severance is found early; however, in the late injuries, preliminary nephrostomy is again the procedure of choice, followed later, after tissue reaction has subsided, by a choice of one of several procedures. If a

segment of the pelvic ureter is absent, a tube may be constructed from the bladder which will bridge the defect (Fig. 14), the ureter may be transplanted to the bladder if the proximity of the

Fig. 14. Diagram illustrating bladder flap operation for bridging of ureteral defect adjacent to bladder.

bladder is such that this procedure can be accomplished without exerting undue tension on the ureter, an isolated ileal loop can be constructed and anastomosed to either end of the ureter, or an ileal pouch may be constructed, but nephrectomy may be the only procedure that can be accomplished in some instances. Ureteral-intestinal anastomosis should be avoided if at all possible; however, the presence of multiple injuries of the bowel may make the use of a transplanted ileal segment feasible. The value of colostomy and adequate diversion of the urinary stream cannot be too vigorously stressed in instances where penetrating wounds involve both bowel and ureter. A diverting and decompressing nephrostomy should be the preliminary step in management of ureteral injuries discovered late, for many times, a reconstruction of the ureter can be accomplished, avoiding nephrectomy. *Many of the surgical injuries to the ureter might well be prevented by preoperative placement of ureteral catheters.*

Injuries of the Bladder

The surgeon's delay and failure to execute prompt and adequate surgery in rupture of the urinary bladder will almost inevitably result in the death of the patient. The wartime surgeon demonstrated by low mortality rates the value of prompt and efficient drainage of the urinary bladder as a necessity in bladder perforation. The bladder, subject to marked variations in its size and shape, and its position as an abdominal organ in the human until approximately the age of twenty, are factors of its susceptibility to injury. The adult bladder is located behind the symphysis pubis in a muscular bed surrounded by the true bony pelvis, anchored distally to the prostate, posteriorly to the seminal vesicles and rectum in the male, and to the cervix and uterus in the female. The anterior fatty and areolar tissue, the space of Retzius with the overlying urachus, and the peritoneum spread well over the dome of the bladder, are important anatomical mechanisms.

As in the kidney, bladder injuries can be classified as either penetrating or nonpenetrating, with the nonpenetrating type being the most common and seen frequently with distortion of the bony pelvis by fracture. The most common nonpenetrating injury is the contusion where damage may be evident only in the serosa, muscle layers, mucous membrane, or all three with the bladder wall remaining intact. This is most commonly seen in the post-partum female, surgery on organs adjacent to the bladder, and with some fractures of the bony pelvis.

The thin distended urinary bladder extending over the symphysis subjected to a sudden blow usually results in an intraperitoneal rupture of the urinary bladder (Fig. 15), for, as the bladder distends, the peritoneal reflection from the anterior abdominal wall to the bladder becomes elevated leaving an extraperitoneal area immediately above the pubis. Continual flow of urine in moderate to large quantities into the peritoneal cavity does not cause peritonitis or serious consequence immediately; however, infected urine introduced into the peritoneum soon produces a violent peritonitis. An occluding effect may occur initially as adjacent omentum and intestine cover the site of the bladder rupture, if the rupture is not too large, producing a temporary partial seal, but this seal becomes ineffective as more urine is secreted from

Fig. 15. Contrast cystogram of classical intraperitoneal rupture of urinary bladder.

Fig. 16. Multiple fractures of the pubic rami producing a large extravascular hematoma and cystogram of intact "tear drop" bladder without rupture.

Fig. 17. Contrast cystogram of combined intraperitoneal and extraperitoneal rupture of urinary bladder.

the kidneys into the bladder, and the rupture again becomes active.

Extraperitoneal rupture occurs in the area of the bladder not covered by peritoneum and is most commonly seen in association with fractures of the bony pelvis below the pelvic brim, particularly the pubic rami and symphysis. The rent is usually made by perforation of bony spicules, but shearing force on the bladder moorings may also produce a tear. All extraperitoneal injuries occur close to the vesical neck on the anterolateral wall of the bladder, and urine extravasates into the space of Retzius and dissects into regions as low as the thighs and as high as the umbilicus. Extravasation of urine has been observed to pass through the greater sciatic notch to the buttocks, the obturator foramen to the thigh, and the inguinal canal to the scrotum as well as extending upward on the abdominal wall. If the urine is infected, the toxic and necrotic action in undrained tissues is fatal; however, sterile urine in a similar situation will produce necrosis and suppuration, but the process is more insidious. Hemorrhage in this area, particularly when secondary to pelvic fracture, can be most severe because of abundant blood supply via the internal pudendal vessels and their branches passing through the urogenital diaphragm, the obturator and superior vesical vessels, the vesical plexus of veins, and the pubic branches of the inferior epigastric artery and obturator artery anastomosing on the posterior surface of the

pubis. Large hematomas develop to distort the shape of the bladder even when bladder rupture is not present and produce, as seen by cystogram, the "tear drop" bladder (Fig. 16).

In perforating injuries, combined intraperitoneal and extraperitoneal rupture (Fig. 17) is usually encountered as the missile passes through the rectum or perineum, and penetrates the intraperitoneal and extraperitoneal areas of the bladder in turn.

The finding of shock and hemorrhage is immediately evident, accompanied by lower abdominal pain, or pain over the pubis, and the patient expresses an extreme desire to void with inability to accomplish the act. Microscopic hematuria, but usually thick blood or clot is found. Pressure applied over the pubic foramen is excruciating, and, classically, compression of the iliac crests simultaneously toward the midline produces severe pain. Bimanual rectal examination reveals a pelvic mass which consists of blood and extravasated urine. The patient seen twenty-four hours or later after an extraperitoneal rupture is feverish and toxic because of the extravasation of urine, and induration and superficial inflammation of the suprapubic area is noted. If there is injury to abdominal viscera and intraperitoneal rupture, there will usually be nausea and vomiting, and, if not, as the extravasation of urine into the peritoneal cavity continues, ileus develops, pain is noted in the epigastrium, chest, or in the shoulder

strap area, and in twenty-four hours there is usually marked distention, vomiting, high fever, and leukocytosis which may mask accurate diagnosis.

If rupture of the bladder is definitely present, surgery must be immediate. The contrast cystogram using 150 to 200 cc.'s of 20 per cent Skiodan with views in the anterior-posterior, oblique, lateral and upright positions provides the only positive diagnosis. Air cystograms, cystoscopy, and the frequently described procedure involving catheterization with injection of measured amounts of fluid into the bladder, and comparing the amount returned, should be forgotten. A urethrogram, to determine the status of the urethra, can be very simply made after the cystogram, by placing a rubber tipped syringe directly into the urethral meatus and injecting the contrast material as the film is being made. Suprapubic cystostomy with careful inspection of the interior of the bladder is completed in the usual manner, utilizing a large four-wing or mushroom type catheter for drainage. If there has been damage to the membranous or prostatic urethra, a splinting catheter should be placed prior to closure. The perivesical and prevesical areas are well drained with numerous Penrose drains.

In intraperitoneal rupture, inspection of the prevesical area prior to opening the peritoneum will show only blood and clots and no urine. The peritoneum should then be opened and the peritoneal cavity thoroughly inspected and cleansed. The tear in the bladder is repaired from the peritoneal side with chronic catgut, and the peritoneum closed without drainage. The bladder is then thoroughly inspected and a cystostomy tube placed. In perineal lacerations of the bladder, the same procedure is followed. However, in penetration of the bladder via the rectum, suprapubic cystostomy is first completed followed by colostomy in order to avoid a vesicorectal fistula. In all instances, failure to remove foreign bodies from the urinary bladder invites formation of bladder calculus, as does the use of silk suture technique for bladder closure.

The complications are many in rupture of the urinary bladder, and particularly so if it is not promptly treated as outlined. A stormy course of peritonitis is usually encountered in intraperitoneal rupture, and this becomes more severe as the time from injury to surgery elapses. Osteomyelitis of the pelvic bones and abscess formation are fre-

quently seen in extraperitoneal rupture and particularly in those that have been poorly drained.

Injuries of the Genital Tract

Injuries of the male genitals are infrequently encountered in civilian practice and present problems of management that require astute judgment as to procedure. The profound shock and hemorrhage of trauma to the deeply placed vital viscera is not seen with genital injuries, but the possibilities of lifelong distress and unhappiness are ever present from mutilations with deformity, testicular injuries with infertility, and penile injuries with defective and painful erections. A post-traumatic urethral stricture may create a wet, miserable, social outcast of a man. General management of genital injuries is fairly well standardized. The causes are many—missiles, knife blades, a well-directed boot, power take-off belts, the sharp edges of the fractured pubic bones, the destructive fall astride a joist, the hideous penetration of impalement, the wounds of war, irradiation reaction, and surgical accidents.

A pair of trousers caught in a tractor take-off, a machine belt from power source, or an unguarded set of gears finds the trousers gone, together with most of the genital skin, one or both testes, and, on rare occasions, the penis itself. If the testes are intact and with adequate blood supply, they must be covered completely after light debridement of the devitalized areolar tissue, removal of all foreign material, and careful cleansing with normal saline. Administration of tetanus toxoid and antibiotics must be routine. With sufficient remaining skin, the scrotum may be reformed in minor injuries and the testes encased in their normal location. A temporary bed for the testes can be made in either thigh or above the pubis for each testicle, if the skin loss is too great. All possible viable skin must be preserved.

The covering of the denuded penile shaft must be done without forming scar contracture, and remaining vital tissues should be carefully preserved and used provided they have a proximal attachment. Skin of the terminal shaft usually remains well attached at the penile corona and should not be used, even if completely viable, unless a broad bridge of uninjured skin extends full length down the shaft and is continuous with the normal skin beyond the area of denudation. A small cuff of normal preputial skin left attached

to the penile shaft, proximal to the corona, will become edematous and an intolerable nuisance. A split thickness graft from the hairless portion of the abdomen or chest is wrapped loosely about the penile shaft with its edges overlapped and sutured in the midline dorsally in a zig-zag fashion to prevent linear contraction of a straight scar. At the base of the penis and at the corona, the edges of the graft are everted and sutured to the adjacent skin, making several cross-cut incisions along the suture line to prevent formation of a constricting band. An indwelling catheter is left in the urethra, and a firm even pressure dressing with an elastic type bandage is applied around the penis. Antibiotic therapy and tetanus toxoid is given, together with large doses of stilbestrol and sedation to decrease or prevent erection.

Punctures, dislocations, contusions, missiles, and the bizarre mutilations of the insane comprise the injuries of the penile body proper. Except in injury of the erect penile body, hemorrhage is rarely massive, and the bleeding can generally be controlled by application of a tourniquet proximal to the protruding ends of two Keith needles placed criss-cross through the penile body. Final permanent control is accomplished by closing the stump of the remaining penis with a continuous suture through Buck's fascia. Subcutaneous hematomas must be promptly drained and the offending vessels ligated, and if the wound is of the penetrating type all foreign material must be removed for, if left in the penile body extensive, fibrosis will occur. Every effort must be made to provide the injured with a properly voiding and normally erect penis, and management should be directed to these objectives. Amputation should not be done except for a well demarcated post-traumatic gangrene. Amputation in the young, as well as in the older male, can be catastrophic to the psyche.

Injuries of the Urethra

Injuries of the urethra are encountered in the use of foreign bodies for sexual gratification of the mentally disturbed, in the use of instruments by the inexperienced or unskilled, and most commonly in the straddle injury and fracture of the bony pelvis. Extraction of the self-introduced foreign body is accomplished easily in most instances by passing an endoscopic sheath into the urethra and with a foreign body forceps in place, grasping and

feeding the object into the sheath and removing the sheath and foreign body as a unit. An indwelling catheter should be placed for a reasonable length of time depending upon the amount of surgical injury and foreign object injury to the urethral mucosa, until all possibility of extravasation of urine is past.

The physician using urethral instruments should be aware of the proper use of the instruments and the consequences that might result from their improper manipulation. Metal catheters should be placed in the rubbish container and only the soft rubber type used. Should a sound or other object used for diagnosis or treatment be pushed through the urethral wall, an attempt should be made to pass a stiletted catheter into the bladder and left indwelling for several days. If this maneuver is unsuccessful, a suprapubic cystotomy should be immediately done to prevent possible extravasation of urine and permit placement of a catheter antegrade per urethrum with cystostomy drainage as well. The use of instruments for dilating urethral strictures should bring to mind the possibility of rupture and extravasation, particularly in the severely strictured male where there is always infection. If rupture is produced, prompt surgical drainage with placement of a urethral catheter must be done to prevent extravasation and formation of a life-taking peri-urethral phlegmon with its gangrenous penile and scrotal skin, profound toxemia, and extravasation to the flanks and abdomen.

In straddle injury of the male urethra, a severe external violent blow to the perineum crushes the thin friable urethra under the edge of the bony arch of the symphysis pubis with such impact that it is commonly severed completely (Fig. 18). The patient may not be aware immediately of his injury, but at the first post-injury voiding he finds little or no urine appearing from the external meatus and the perineum filling with urine. Fortunately, sufficient spasm of the sphincteric mechanism occurs in many individuals, and they are unable to void and are first seen in acute retention. If the lumen remains intact, a catheter may be very easily passed into the urinary bladder and, if this can be accomplished, it should be left indwelling for a minimum of fourteen days.

The most ideal conditions for control of ruptured urethra occur prior to the presence of urinary extravasation. If a catheter is passed to the

point of injury where the urethra has been completely severed and cannot be passed beyond this area, a suprapubic cystostomy must be immediately undertaken to prevent extravasation. At surgery

Fig. 18. (above) Diagrammatic representation of rupture of urethra distal to triangular ligament with extravasation of urine to abdominal wall, perineum, shaft of penis, and scrotum.

Fig. 19. (below) Rupture of urethra proximal to triangular ligament with extravasation limited to perivesical area.

an attempt must be made to re-establish the continuity of the urethral lumen, and an indwelling catheter as well as a suprapubic cystostomy tube placed.

When the urethral rupture has already been complicated by urinary extravasation from a straddle injury, the triangular ligament of the perineum, the pelvic bones, and the abdominal wall all attempt to keep the urine outside the body cavity. The extravasation is sharply limited in the perineum and external genitals by the anatomic barrier of the union of Colles fascia with the sheath of the transverse perineal muscle, and the fascia of the inner thighs at the crease of the groin. As time passes, extravasation fills the scrotum and the shaft of the penis and the classic picture is noted. Radical drainage to the abdominal wall,

the perineum, shaft of the penis, and skin of the scrotum is performed by breaking down all of the tissues with the finger and placing too many rather than too few drains. Suprapubic cystostomy must also be done with an attempt to place a catheter per urethrum by introducing interlocking sounds. If the severed ends of the urethra should be identified at the time of perineal drainage, an attempt to unite them is usually futile and, instead, one should rely on the remarkable regenerative activity of the urethral mucosa over an indwelling catheter for two or three weeks to establish continuity of the urethral lumen.

Uncommonly, straddle injury with fracture of the pubic arch may sever the body of the prostate at the triangular ligament (Fig. 19), and, similarly, the patient is unable to void and a catheter is passed with futile attempts to obtain urine. On rectal examination, the prostate can be felt elevated out of its usual position and displaced by a soft mass consisting of blood and urine extending well into the rectum. Signs of urinary extravasation in the perineum and genital region characteristic with urethral rupture external to the triangular ligament are not present, for the extravasation is confined internal to the triangular ligament similar to a rupture of the bladder. Immediate cystostomy with removal of all extravasated blood and urine with breakdown of all septa by the finger and placement of multiple drains is the fundamental procedure. With interlocking sounds, the ends of the severed urethra can be identified and an indwelling bag type catheter placed per urethram, with external traction of at least one pound exerted on the catheter to draw the fractured and dislocated bladder neck into proper position internal to the triangular ligament. To depend on the latex bag to hold the ends in apposition is folly, and several anchoring sutures of heavy catgut should be placed through the prostate and tied in the perineum over small pieces of rubber tubing. The possibility of intraperitoneal injury is very real, and the peritoneal cavity should be explored as well at this time.

The patient should be impressed with the requirement for lifelong postoperative observation in management of urethral injuries, for stricture in the injured area of the urethra is inevitable, requiring repeated serial dilatations and, in many, internal urethrotomy.

Injuries of the Testes

Violent destructive injuries of the testicle occur with scrotal avulsion and gunshot wounds, and concentrated effort must be made to conserve the remaining testicular tissue. Total rupture or severe crushing of the testicle is a morbid problem, occasionally complicated by massive hematoma formation which may mask the extent of the injury. Testicular atrophy usually results even if the blood supply of the testicle is not seriously damaged by virtue of the frailty of the spermatogenic tissues themselves. Pain of testicular injury is intense and profound shock, out of proportion to the degree of hemorrhage, is characteristic. In non-penetrating injury with moderate hematoma formation, bedrest, adequate scrotal support, ice packing, antibiotics, tetanus toxoid, and sedation are usually all that is required. A similar regimen is used in the penetrating injuries, provided there is no foreign body present and hemorrhage is minimal. Penetrating or nonpenetrating testicular injuries with massive scrotal hemorrhage must be explored to evacuate clots, control the bleeding, and suture the testicular tunics if it is felt that the testicle is viable. In bilateral injury, if one testicle is totally lost every effort should be made to save the testicle with the lesser injury, no matter how badly damaged it may appear. In mumps orchitis, androgenic activity of the atrophic testicle remains, but with the atrophy of injury, replacement therapy of synthesized male hormone, testosterone, must be given as a sublingual tablet or implanted subcutaneously in pellet form every two to three months to prevent hypogonadism. Torsion of the cord of the injured testicle can be prevented by single suture fixation of the testicle to the scrotum, at the time of surgery. Postoperative hematoma formation with its practically limit-

less extension into the loose aerolar tissue of the scrotum can be prevented by extremely meticulous ligation of all bleeding areas. A compressive dressing with continuous ice pack, in addition to precise hemostasis, will prevent hematoma formation, but if hemorrhage and swelling continues, the scrotum must be reopened and all blood clots removed and hemostasis secured.

Summary

The various causes and types of genito-urinary tract injury and treatment of these injuries is discussed.

Awareness of the possibility of damage to the urinary tract is the most important factor in the patient with multiple injuries or in the patient subjected to radical pelvic or abdominal surgery.

A careful history and physical examination, coupled with appropriate laboratory and radiographic studies, will make the proper diagnosis and direct the treatment necessary.

Damage to other organs frequently accompanies trauma to the urinary tract, and may require priority of surgical management.

POST-TONSILLECTOMY MORBIDITY

The value of a new antibiotic-analgesic chewing troche on the postoperative course in tonsillectomy in sixty-four patients was recently assessed. The new preparation (Orabiotic®) is a chewing gum troche containing 3.5 mg. neomycin, as the sulfate; 0.25 mg. gramicidin, and 2.0 mg. propesin.
